September 13, 2012

Rebecca J. Cronkhite, Planning Manager Alaska International Airports System Department of Transportation & Public Facilities PO Box 196960 Anchorage, Alaska 99519

Dear Ms. Cronkhite:

Alaska International Airport System (AIAS) Forecast

This letter is in response to your request for the Federal Aviation Administration's (FAA) review of the June 5, 2012, Alaska International Airport System Forecast. This request included the review of the individual forecast summaries for:

- Fairbanks International Airport (FAI) dated June 5, 2012
- Lake Hood Seaplane Base (LHD) dated August 17, 2012
- Ted Stevens Anchorage International Airport (ANC) dated June 5, 2012

We reviewed the AIAS Forecast and individual forecasts for the above airports in consultation with our National Planning & Environmental Division. We understand this document was prepared along with the on-going State System Plan efforts. At this point in time, there is no development expected to require an Environmental Impact Statement or a Benefit Cost Analysis at any of the three airports.

The total operations annual growth rates for the AIAS and individual summary forecasts for the above airports are consistent with the FAA Terminal Area Forecast (TAF). We find adequate justification exists for the forecast baseline figures and hereby approve the AIAS Forecast Summary and individual Summary Forecasts for FAI, LHD and ANC.

We look forward to working with you as you continue to develop the remaining components of the AIAS Plan.

Sincerely,

Gabriel Mahns Airport Planner FAA, Alaskan Region

AIAS Airlines Airport Affairs Committee

Ted Stevens Anchorage International Airport - Fairbanks International Airport

July 5, 2012

Mr. Steve Hatter Deputy Commissioner of Aviation 4111 Aviation Avenue P.O. Box 196900 Anchorage, AK 99519-6960

Re: AIAS Planning Study Forecasts

Thank you for the opportunity to participate in the development and review of the forecasts for Ted Stevens Anchorage International Airport, Lake Hood Seaplane Base, and Fairbanks International Airport. We appreciate the extensive effort made by the AIAS Planning team to reach out and actively solicit airline participation in the process.

The AIAS (Alaska International Airport System) AAAC (Airlines Airport Affairs Committee) believes these forecasts accurately represent current economic uncertainties and trends and are a reasonable estimate of long term future activity levels. Given uncertainties of forecasts, especially today, we encourage future planning to be based on aviation activity trigger points rather than forecasted dates. We also believe the forecasts will need to be revisited prior to committing to any large capital projects.

Thanks again for partnering with the airlines on the forecasts. We look forward to working with you on the Airport Master Plans.

Best Regards,

Kathy Smith Co-Chairperson AIAS Airlines Airport Affairs Committee

win Holfmann

Kevin Hoffmann Co-Chairperson AIAS Airlines Airport Affairs Committee

ALASKA INTERNATIONAL AIRPORT SYSTEM PLAN Forecast Technical Report

This report summarizes the approach, assumptions and results of the aviation activity forecasts prepared for the Alaska International Airport System (AIAS). The AIAS includes the two major international airports serving the State of Alaska, Ted Stevens Anchorage International Airport (ANC) and Fairbanks International Airport (FAI). Forecasts for Lake Hood Airport (LHD), encompassing both the seaplane base and the strip, are included because of its close proximity and interaction with ANC.

Forecasts are presented for 2015, 2020, 2025, and 2030. The forecasts for near term (through 2015), intermediate term (2020) and long term (2030) are carried forth in more detail to facilitate follow-on capacity analysis. The document first describes the purpose and background of the forecasts. Next, a description of key socioeconomic and aviation industry factors is provided, along with an examination of historical aviation activity within the AIAS. The document continues with detailed projections of passenger and cargo activity, followed by forecasts of other activity categories, including air taxi, general aviation (GA) and military. The document concludes with a comparison with the Federal Aviation Administration's (FAA) 2011 Terminal Area Forecast (TAF) and a set of alternative forecast scenarios. In addition, the document is supported by several technical appendices, Appendix A through Appendix L.

1.0. Purpose and Background

The AIAS forecasts have been prepared in support of the AIAS Planning Study, as part of the AIAS' overall strategic planning effort. The purpose of the planning effort is to outline initiatives to strategically position AIAS's standing in the international air cargo and passenger industries, explore the use of incentives and to help maximize use of the System's assets and enhance its long-term financial viability. The forecasts also support the AIAS Strategic Plan which lays out the mission, vision, and values of the AIAS, and summarizes its operating context, external challenges, opportunities, and strategic initiatives. Finally, the forecasts are used in the ANC and FAI Master Plan Updates along with the ANC Part 150 Study.

More specifically, the AIAS forecasts are intended to help determine the capacity of the AIAS system in order to: (1) explore options for transferring aviation activity between the two airports to optimize use of existing capacity; and (2) determine trigger points for adding new capacity to the system if needed. To assist in the capacity modeling analysis, the forecasts were used to prepare design day flight schedules for ANC and FAI. The baseline forecasts do not incorporate the impacts of capacity constraints or incentive programs and therefore assume that the AIAS airports will continue in their current roles. The impact of capacity constraints is addressed in one of the scenarios in Section 11.

As part of the forecast process, a forecast methodology and a set of forecast assumptions were prepared for review and approval by the State of Alaska and other

stakeholders. In addition, a comprehensive survey of the major passenger and cargo carriers serving ANC and FAI was undertaken. These are described in more detail below.

1.1. Forecast Methodology

After review and comment by the State and other stakeholders, the AIAS forecast methodology was set forth in <u>Technical Memorandum #1: Final Recommended</u> <u>Methodology for Preparing Aviation Demand Forecast for the AIAS Plan</u> finalized on August 5, 2011. A draft version of this memorandum was submitted to the State, airlines, FAA, and their representatives for review and approval and the final memorandum incorporated the comments that were received.

This technical memorandum describes the proposed baseline forecast approach for each of the main activity categories, including air cargo, passenger, air taxi, general aviation, and military. It also provides the methodology for preparing the design day flight schedules and recommended forecast scenarios. In addition, the memorandum included a detailed description of the deliverables that will be provided as part of the forecast effort, and how they relate to concurrent planning initiatives at ANC, FAI, and LHD.

Relevant portions of the forecast methodology memorandum have been incorporated within the individual sections of this document and the memorandum is also included in its entirety as Appendix J.

1.2. Survey of Air Carriers

A survey of passenger and cargo carriers was performed in the late summer and fall of 2011. The effort included separate surveys for passenger and all-cargo carriers. Surveys were first mailed out to carriers with follow-up phone calls and e-mails to encourage response.

Key findings from the cargo surveys are summarized in the <u>Anchorage Cargo Carrier</u> <u>Summary</u> dated January 2, 2012. The all-cargo carriers that were surveyed are broadly classified as:

- Intrastate: e.g., Northern Air Cargo with 100% locally originating domestic cargo;
- Intercontinental Tech Stop ("Gas & Go"): e.g., Evergreen, with no or only nominal deplaned and/or enplaned cargo; and
- Intercontinental Hubbing: e.g., FedEx and UPS with virtually all cargo deplaned and re-enplaned at ANC.

The survey was intended to be completed independently by recipients, as well as to be used in phone interviews. The advantage of the latter was to ask follow-up questions and to gather meaningful intelligence that may not have been elicited by the written survey questions. With repeated requests, response rates were relatively high (exceeding 50% of contacts) for the surveys but fewer were willing to participate in interviews despite the consultants' assurances that the two would not be wholly redundant.

Although the consultants explained to survey respondents the requirements of a twentyyear forecast, the latter generally were not comfortable in providing projections given recent air cargo history. For example, the last decade, a period in which growth was projected to exceed the capacity of several traditional U.S. gateways, instead found those airports with less annual air cargo in 2010 than they tallied a decade earlier. The late 2011 cargo downturn caused individual transpacific carriers and even institutions such as IATA to revise their forecasts for the remainder of the calendar year. As a result, carriers were uniformly non-responsive when asked for long-term forecasts. Only a few would even give thoughtful responses to the five year forecast while others simply suggested using the Boeing forecasts.

Although the carriers were mostly unable to provide forecasts of future tonnage at AIAS airports, they provided useful information on future fleet mix, insights into current facility and operational issues, and the relative advantages and disadvantages of operating at ANC vs. FAI.

1.3. Forecast Assumptions

Following some initial forecast analysis and receipt of the majority of the surveys, a set of forecast assumptions was prepared for review and approval by the State and selected stakeholders. The assumptions are fully described in the <u>AIAS Recommended</u> <u>Forecast Assumptions</u>, dated December 19, 2011 and attached as Appendix K.

The forecast assumptions were used as inputs to the aviation forecasts elsewhere in this document and to provide a context for forecast preparation. The assumptions were reviewed by the AIAS Planning Study consulting team, by the airlines, and by representatives of the State, ANC and FAI, and comments and recommendations were incorporated. The purpose of the assumptions was to provide a reasonable assessment of the key forecast trends and parameters necessary to generate activity forecasts. In many instances, multiple outcomes for these trends and parameters are possible. Therefore, up to four forecast scenarios will be prepared later in the study to address the impact of potential variations in these factors.

The input assumptions should not be confused with the aviation activity forecasts. The forecasts are the output of a process in which input assumptions are incorporated in a methodology/approach that generates the aviation forecast numbers. The specific assumptions and methodologies used to develop the forecasts have been incorporated into this document in the sections where they are most relevant.

2.0. Socioeconomic Background and Projections

The ultimate determinants of passenger and air cargo demand are the strength of the economy and the cost and availability of service. Consequently, a clear understanding of local, national, and international economic forces and trends is important for developing an accurate aviation activity forecast. This is particularly true for Anchorage, Fairbanks, and Alaska. Due to the State's large size, the remote location of many communities, and the limited road system, aviation assumes a role typically undertaken by highways and rail elsewhere in the country. Thus, a healthy aviation system is vital to the continued growth of the Anchorage, Fairbanks, and Alaska economies.

Historical data on population, employment, and income in the primary study area are presented in Tables A.1 through A.4 of Appendix A and discussed in this section. The Anchorage Metropolitan Statistical Area (MSA) which contains the Municipality of Anchorage and the Matanuska-Susitna Borough, and the Fairbanks MSA which includes the Fairbanks North Star Borough, were selected as the primary service areas for this study. Data for the remainder of Alaska and the United States as a whole are also provided.

The principal source of historical data for the two MSAs, the State of Alaska, and the United States was the U.S. Department of Commerce's Bureau of Economic Analysis (BEA).

Three sets of socioeconomic forecasts were considered for use in this study, including:

- Woods & Poole, Complete Economic and Demographic Data Source (CEDDS);
- Alaska Department of Labor and Workforce Development (DOL), <u>Alaska</u> <u>Population Projections: 2010 to 2034</u>; and
- Institute of Social and Economic Research (ISER), <u>Economic and Demographic</u> <u>Projections for Alaska and Greater Anchorage 2010-2035</u>.

Woods & Poole (W&P) is an economic forecasting firm that publishes annually updated economic and demographic forecasts for each state, metropolitan area, and county in the United States. Its advantage is that it is a comprehensive and up-to-date source that provides forecasts for all major economic metrics such as population, employment and income. Its disadvantage is that it does not have the insight into Alaska's conditions that local organizations possess.

The Alaska Department of Labor's Population Projections are current, having been published earlier in 2011, and reflect in-depth knowledge of the State. The projections, however, are limited to population and do not include employment or income.

The ISER report contains forecasts of population, employment and income for Alaska, the Municipality of Anchorage and the Matanuska-Susitna Borough, but includes no information for Fairbanks. Its population forecasts are higher than those prepared by

either W&P or the Alaska Department of Labor, but despite higher population forecasts its income forecasts are more conservative than W&P.

2.1. Population

Table A.1 in Appendix A shows historical population for the two MSAs, the rest of Alaska, and the United States. As shown in the table, the population of the Anchorage MSA grew at an average annual rate of 1.8 percent between 1990 and 2010, from 267,762 to 380,821, while the Fairbanks MSA grow at about 1.1 percent per year over the same time. Growth has been slowest in the more rural parts of Alaska, outside the two metropolitan areas. Many of these areas have been subject to significant outmigration as younger members of the population move to more urban areas to seek out better employment.

Table 2.1 presents the three available alternative population forecasts. The State DOL population projections are recommended for use in this study. They are very similar to W&P for the Anchorage and Fairbanks metropolitan areas but appear to better reflect the ongoing outmigration from more rural areas of Alaska.

The selected forecasts project a continuation of historical trends but at a slower pace as the average age of the population increases and fewer people are of child-bearing age. As shown, population in the Anchorage metropolitan area is projected to increase by 1.3 percent per year, compared to 0.6 percent for Fairbanks, and 0.9 percent for the United States. The remainder of Alaska is expected to achieve very little growth, about 0.1 percent per year.

None of the above forecasts are sufficiently current to incorporate the recently announced potential force structure changes at Eielson Air Force Base near Fairbanks, which may result in a reduction in personnel, as well as associated population and employment.

2.2. Employment

Table A.2 in Appendix A presents historical employment for Anchorage, Fairbanks, the rest of Alaska, and the United States. Historically, employment has grown more rapidly than population. Over the 1990-2009 period, the average annual growth rate for employment in Anchorage and Fairbanks has exceeded that of the United States. Major employers in the area are oil and gas production, tourism, mining, timber and agriculture.

Table 2.2 presents three alternative employment forecasts. For employment projections, a hybrid approach that applies the per capita employment projections from the W&P forecasts to the State DOL population projections was selected. This approach helps maintain consistency with the population projections, especially with respect to the relative growth rates between Anchorage, Fairbanks and the remainder of Alaska.

Employment Forecasts

(a) Includes Municipality of Anchorage and Matanuska-Susitna Borough. 2010 data estimated based on State growth rates.

(b) Includes Fairbanks North Star Borough. 2010 data estimated based on State growth rates.

(c) Growth rates from Woods & Poole, Complete Economic and Demographic Data Source (CEDDS) applied to 2010 base year data from Table A.2.

(d) Growth rates from Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035, by Institute of Social and Economic Research and Northern Economics, December 2009, applied to 2010 base year data from Table A.2.

(e) Woods Poole employment to population ratios applied to Alaska Department of Labor Population Projections from Table 2.1

Future employment is projected to grow less rapidly than in the past for several reasons. First, as the average age of the population increases, more people retire and therefore drop out of the labor force. Second, because of a current glut in natural gas supplies within the United States, the incentive for further natural gas development, at least in the short term, is reduced. Finally, the Federal government, which is a major employer in Alaska, is under strong pressure to reduce spending, which will likely result in reduced employment in that sector.

In contrast to the last 40 years in which basic (oil, timber, etc.) and infrastructure (pipeline construction, etc.) industries were the primary drivers of the State economy, future employment growth is projected to occur mostly in support industries such as trade, finance, and services. Basic and infrastructure industrial activity tends to be in rural areas, and support industries in urban areas. Hence, future employment in Anchorage and Fairbanks is projected to grow faster than in the remainder of the State.

Tables A.3 and A.4 in Appendix A show historical annual real total and per capita personal income (in 2010 dollars) for Anchorage, Fairbanks, the rest of Alaska, and the United States. Total personal income in the Anchorage and Fairbanks MSAs grew slightly faster than in the United States between 1990 and 2009. Trends in historical income have been similar to those in employment. When employment has grown quickly, income has grown quickly. In slower periods, such as the mid-1990s, real income has grown much more slowly.

Between 1990 and 2009, real per capita income in the Anchorage and Fairbanks metropolitan areas alternately declined and rose, along with the fortunes of the oil industry. Although per capita income in Anchorage, Fairbanks, and elsewhere in Alaska is still higher than the remainder of the United States, the difference has diminished over the past two decades.

Table 2.3 shows income projections for Anchorage, Fairbanks, the remainder of Alaska, and the United States. A hybrid approach, similar to that used for employment, was selected for income. This involved applying the average of the ISER and W&P per capita income projections (Table 2.4) to the State DOL population projections. The W&P income projections were considered too aggressive by regional economic development experts familiar with Alaska. The ISER projections, on the other hand, have a history of being conservative. Therefore, taking the average of the two forecasts was considered a reasonable compromise.

Consistent with the population and employment projections, the adjusted income forecasts project Anchorage and Fairbanks income to continue to grow but not as quickly as in the past. As shown in Table 2.3, Anchorage and Fairbanks metropolitan income is projected to grow less quickly than in the United States, in part because of reduced stimulus from natural gas development and Federal expenditures.

Table 2.3 Personal Income Forecasts (000's of 2010 Dollars)

(a) Includes Municipality of Anchorage and Matanuska-Susitna Borough. 2010 data estimated based on State growth rates.

(b) Includes Fairbanks North Star Borough. 2010 data estimated based on State growth rates.

(c) Growth rates from Woods & Poole, Complete Economic and Demographic Data Source (CEDDS) applied to 2010 base year data from Table A.5.

(d) Growth rates from Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035, by Institute of Social and Economic Research and Northern Economics, December 2009, applied to 2010 base year data from Table A.3.

(e) Average of Woods & Poole and ISER per capital income projections (Table 2.4) applied to Alaska Department of Labor Population Projections from Table 2.1. Rest of Alaska calculated by subtracting Anchorage and Fairbanks MSA totals from State totals.

Table 2.4 shows projected real per capita income for Anchorage, Fairbanks, the rest of Alaska, and the United States. Like income, per capita income is projected to grow more slowly in Alaska than elsewhere in the U.S. As a result by 2030 average per capita income in Fairbanks is projected to be slightly lower than in the U.S. and higher by a much smaller margin in Anchorage.

There were some concerns that using a 2009/2010 base year during the middle of an economic downturn may negatively bias the projections. However, the large amount of public debt and anticipated reductions in government spending will likely reduce the rate of future economic growth, so the period of rapid recovery experienced after previous downturns is less likely to occur this time.

2.3. Global Economic Forecasts

Much of the cargo traffic at the AIAS airports depends primarily on world economic trends rather than local or national trends. Global Insight forecasts of Gross Domestic Product (GDP) by world region, as published in the <u>FAA Aerospace Forecasts: FY 2010-2031</u>, and shown in Table 2.5 were selected for use in the international cargo forecasts. They are the most recent available forecasts that cover all the regions in question.

China, along with Asia/Pacific countries outside of Japan, is anticipated to continue the rapid growth it has experienced in the past. Japan, with its mature economy and aging population, is projected to grow much more slowly.

GDP Forecast by Region (millions of 2005 US Dollars)

Source: Global Insight, as published in FAA Aerospace Forecasts: 2011-2031, March 2011.

3.0. Fuel Costs and Air Fares

Jet fuel prices are an important determinant of aviation demand and will be incorporated in both the passenger and cargo forecasts. Jet fuel prices are very sensitive to crude oil prices which have been extremely volatile over the past several years. Several forecasts of jet fuel and crude oil prices were considered. Airlines need to cover their fuel costs, so jet fuel prices have a direct impact on air fares and freight rates as well.

3.1. Oil and Jet Fuel Prices

Jet fuel costs, along with other fuel costs, are generally higher in Alaska than elsewhere in the United States for a variety of reasons including higher refining costs, higher transport costs, and the expense of Alaska insurance and spill response costs. According to the AirNav Fuel Price Report, in April 2012, fixed base operator (FBO) jet fuel prices at Alaska were 6 percent higher than elsewhere in the United States. Commercial airlines have their own fueling arrangements so their costs vary from the FBO costs, but the airlines indicate that the Alaska fuel price differential is still a factor for them.

Although hard data are not readily available, anecdotal evidence is that the Alaska fuel price differential has always been a factor, and is expected to remain a factor through the foreseeable future. There are future circumstances that may change the degree to which jet fuel prices in Alaska differ from those elsewhere in the United States, including:

- Current Asian excess jet fuel refining capacity may diminish, reducing the competitive pressure that is restraining Alaska jet fuel prices from increasing even more than is presently the case;
- The Jones Act, which requires that fuel shipped from a U.S. port to Alaska be carried on U.S. flag vessels (which are more expensive than foreign flag vessels), could be altered, either increasing or decreasing the Alaska jet fuel price differential; and
- Regulatory or tax rate changes within Alaska or the U.S. could alter the current Alaska jet fuel price differential.

Although the above factors will have an influence on Alaska jet fuel prices, the main determinants will continue to be the global demand and supply factors that affect fuel prices throughout the world.

As noted earlier, there is no available data base of average Alaska jet fuel prices that spans the historical period. Likewise, there are no available long-term forecasts for jet fuel prices specific to Alaska. For these reasons, U.S. jet fuel price data will be used as a proxy for Alaska jet fuel price data in subsequent analyses. As long as the relationship between Alaska and U.S. jet fuel prices remains approximately the same, this will not affect the forecasts. The Alaska jet fuel cost differential is incorporated into

the historical relationships used to develop the forecast equations and is therefore automatically carried forward into the forecasts.

There is significant uncertainty associated with future jet fuel prices, due to local, national, and global factors. Therefore, high and low fuel price forecast scenarios will be prepared that show the impact on aviation activity levels resulting from changes in the baseline fuel assumptions.

Table 3.1 shows the volatile history of U.S. jet fuel prices over the last ten years. Between 2000 and 2011, jet fuel prices almost tripled in real terms. Within that term, there were sharp fluctuations as well. Oil prices peaked in mid-2008 and then plummeted during the ensuing financial crisis. By 2011, they had returned to levels close to those in 2008.

Table 3.1

Historical Average Jet Fuel Prices

| | Jet Fuel Price | 2010 |
|------|----------------|---------|
| Year | Nominal | Dollars |
| 2000 | \$0.85 | \$1.05 |
| 2001 | \$0.73 | \$0.88 |
| 2002 | \$0.69 | \$0.82 |
| 2003 | \$0.82 | \$0.97 |

| 2011 | \$2.94 | \$2.87 |

Sources: U.S.Department of Energy Spot Prices for U.S. Oil and Petroleum Products and HNTB analysis.

Table 3.2 presents alternative scenarios for future crude oil and jet fuel prices. The United States Department of Energy (DOE) and the FAA provide specific forecasts of jet fuel prices. In general, the DOE projects oil and jet fuel prices to increase gradually in their Reference case and much more rapidly in their High Oil Price scenario. The FAA's estimate anticipates a gradual increase through 2015 and then a decline. In their forecast for Anchorage and Alaska, ISER assumed a cost of \$95.00 per barrel in 2009 prices (\$96.69 in 2010 dollars) throughout the forecast period. As of this writing, crude oil and jet fuel prices have been tracking higher than most forecasts had indicated. As

of September, 2011, actual jet fuel prices were close to the DOE high forecast, whereas as of November 11, 2011, spot crude oil prices were \$98.18 per barrel, higher than the FAA or base DOE forecasts and close to the ISER forecasts.

A compromise projection was developed, with the input of those stakeholders that reviewed the forecast assumptions. The selected jet fuel price forecast assumes that fuel prices will grow gradually in real terms to the average of the DOE Reference and High forecasts by 2015, and then continue to grow at the average of the DOE Reference and High cases thereafter. This assumption incorporates the continuing tendency of fuel prices to track higher than most forecasts but does not completely accept the DOE High forecast which was intended to represent an extreme case.

| | Jet | Jet Fuel Costs per Gallon (per gallon) | | | | Crude Oil Prices (per barrel) | | | |

(g) Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035, by Institute of Social and Economic Research and Northern Economics, December 2009. Converted to 2010 prices.

It is assumed that ANC, FAI, and the airlines will continue to take whatever measures are necessary and install whatever facilities are required to avoid a recurrence of past fuel availability issues and to ensure that jet fuel is available to the carriers at market rates.

The possibility that fuel availability may constrain growth in airport activity, and the measures that ANC and FAI can take to ensure fuel availability, will be addressed in more detail in the incentives study as part of the strategic plan to be prepared after the forecast.

3.2. Average Air Fares

Locally originating passenger activity is sensitive to local economic factors such as population, employment, and income, and also to airline factors such as air carrier service and fares. Therefore, the critical assumptions for this analysis include the use of both the growth rates identified in Section 2 for socioeconomic data and on assumptions regarding future yield (revenue per passenger mile) and fare levels.

Tables B.1 and B.2 show the history of the real cost of average air fares at ANC and FAI since 1990. Over the long term, average fares at ANC, FAI, and the United States have declined markedly in real terms. Historically, these declines have been sustained by increases in airline efficiency, reduced labor costs, and increased load factors which have allowed aircraft operating costs to be distributed over more passengers.

Although average air fares to the rest of Alaska are similar for ANC and FAI, passengers at ANC have consistently enjoyed lower air fares to the Lower 48 than passengers at FAI. Tables B.3 and B.4 show average yield (revenue per passenger mile) for the two airports. The data show that, even when adjusted for the increased distance between FAI and the Lower 48, ANC passengers enjoy a price advantage.

Table B.5 provides the FAA forecasts of yields and fares. An estimate of FAA fares was derived by multiplying the FAA forecasts of average yield and average trip distance. Since the FAA provides separate forecasts for mainline and regional carriers, these were weighted by FAA-forecasted enplanements to generate combined mainline-regional carrier fare projections. As shown in the Table, the FAA projects yield to continue to decline but, because of increasing trip distance, average U.S. fares are projected to decrease at a slower rate.

As noted earlier, the FAA forecasts are based on an optimistic outlook for jet fuel prices (see Table 3.2). Table B.6 presents an adjustment to FAA yield projections that incorporates the jet fuel cost projections selected earlier in this section. These adjusted yield projections were used to prepare average fare projections for ANC and FAI shown in Table 3.3. The fare projections indicate that the historical decline in real air fares will reverse, resulting in future gradual increases, driven by higher fuel prices. Unlike the past, it is unlikely that higher fuel prices will be offset by higher load factors since loads are already close to 100 percent.

The projections in Table 3.3 represent average air fares, and assume that fuel and other operating costs will prevent fares from sinking significantly below these levels and that airline competition will prevent them from rising significantly above these levels. In reality, there will be short term fluctuations in fare levels in response to airline marketing and operational initiatives. In addition, the averages listed above will encompass a broad array of air fares, ranging from advance purchase economy class fares to last minute purchase business class fares.

| FAA | | FAA | | ANC Outbound Fares (dollars) | | | FAI Outbound Fares (dollars) | | |

4.0. Historical Aviation Activity at AIAS Airports

This section discusses historical aviation activity at AIAS airports including a discussion of the data sources. Aviation activity is comprised of the following subcategories:

- Commercial Passenger Service Activity Including enplaned, deplaned and transit passengers for domestic air carriers, regional carriers, charter and other carriers, and international carriers;
- Air Freight and Mail Activity Including enplaned, deplaned, and transit tonnage operations for domestic and international carriers;
- Air Taxi and Other Activity Including small, for hire operators, and some other commercial operators that are not classified as passenger or cargo operators in the traditional U.S. DOT data sources;
- General Aviation Activity; and
- Military Operations.

Passenger activity is organized into three main categories: intrastate; other U.S.; and international. These breakouts recognize the different forces driving activity in each region. Within Alaska, air transportation is a necessity. Many Alaska communities do not have access to other transportation modes such as highway and rail. Air travel to or from rural Alaska is dictated by necessity, so compared to many other regions in the U.S. demand for air transportation within Alaska is relatively price inelastic. Travel between Alaska and the remainder of the U.S. is more discretionary since alternative transportation modes are available. Also, many Lower 48 passengers to Anchorage are tourists who have a range of options for travel destinations. Hence, air travel to the rest of the U.S. and to other countries is much more price-sensitive.

Air cargo at the AIAS airports includes the following:

- Intrastate cargo to and from other Alaska airports;
- Origin-destination cargo flows from AIAS airports to and from the Lower 48;
- Origin-destination cargo flows from AIAS airports to and from other countries;
- Transfer cargo cargo that is unloaded from one airplane and loaded to another airplane this can be foreign to Alaska, foreign to other U.S., or Alaska to other U.S; and
- Transit cargo cargo that is neither loaded nor unloaded at AIAS airports but is carried on aircraft that land at AIAS airports for refueling or crew relief.

Available data sources do not provide an accurate breakout between origin-destination, transfer, and transit cargo; however, when surveyed, cargo operators indicated that origin-destination cargo flows from AIAS airports to and from other countries were minor, accounting for less than 1 percent of the total.

The two main sources of information on historical and current aviation activity at the AIAS airports are the airports themselves and the U.S. Department of Transportation (US DOT). Each source has advantages and shortcomings.

Airport records have historically been more inclusive for passenger activity. Until 2003, the US DOT data missed many of the smaller intra-state carriers. In addition, the US DOT data provide inbound and outbound passenger counts but with no breakout of enplaned, deplaned, and transit passengers. Unlike the US DOT data, the Airport data include both non-revenue and revenue passengers. Unlike the Airports' data, The US DOT data have the advantage of providing market-by-market breakouts of passengers. In addition, some carriers fail to provide complete data with the Airport on a consistent basis. For example, in 2005 an international carrier did not file any enplaned or deplaned passenger data to the Airport, even though they had done so in previous years and continued to provide service to ANC in 2005. Likewise, another international carrier filed no transit passenger information in 2005, despite having done so in previous years. Both carriers filed passenger data with the US DOT in 2005.

There are similar gaps in the cargo data. The international carriers, in particular, have not been consistent in the way they report transit and transfer cargo activity. True transit cargo is cargo that remains on the aircraft without being off-loaded and is primarily carried by aircraft that use ANC as a technical stop to refuel and change crews. Some airlines record transfer cargo (cargo that is off-loaded from one aircraft and loaded onto another aircraft) as enplaned and deplaned cargo, whereas others report it as transit cargo. Comparisons of historical transit cargo data with all-cargo aircraft landed weight statistics suggest that true transit cargo has been under reported in the past, although the airlines have made progress in reducing this problem. Gaps also exist in the US DOT data. Until 2003, many of the carriers, including most of the U.S. flag all-cargo carriers, did not file cargo tonnage or aircraft operations data.

As is the case with passengers, gaps remain in the cargo data airlines provide to the Airports. For example, some carriers do not report transit cargo, while others appear to report transit cargo twice, both on the inbound and outbound legs. Other carriers report significantly more cargo tonnage to the U.S. DOT than to the Airports. Further confusion occurs when one carrier contracts the services of another carrier to carry cargo. In these instances, one carrier may report activity to the Airports while the other carrier reports activity to the US DOT.

In general, the Airport passenger and cargo data show more consistency over time, especially for domestic operations. Since 2003, the US DOT data appear to be more comprehensive with breakouts on a market basis. Consequently, the US DOT T100 data are used for the analyses that require market-by-market detail.

4.1. Historical Passenger Activity

The recent history of passenger activity at ANC and FAI, including originating, enplaning, deplaning and transit passengers, is discussed in this section. Originating passengers are passengers that begin their air trip at ANC or FAI. Enplaning passengers include originating passengers plus those passengers that transfer from

another aircraft. Transit passengers either remain on the aircraft or deplane and enplane the same aircraft as it makes a stop at ANC or FAI.

Table 4.1 summarizes historical enplaning, deplaning, and transit passengers at ANC. More detailed breakouts of these data are provided in Tables C.1 through C.3 in Appendix C. The data in the appendices are organized by domestic commercial carrier, "for hire" air taxi, and international. This information was compiled according to airline. Some airlines, such as Northwest (now Delta) and Alaska Airlines, have provided both domestic and international service over the historical period; however, since most of their service was domestic their passengers were included in the domestic category.

In general, domestic enplaning and deplaning passengers at ANC have experienced slow growth in recent years with downturns during economic recessions. More notably, the number of transit passengers has declined significantly. The number of domestic transit passengers has declined significantly as airlines in Alaska, as in the rest of the United States have sharply reduced their multi-stop and tag end routes.

Domestic air taxi and other enplanements and deplanements have experienced year-toyear fluctuations with a sharp decline during the 2008 financial crisis and a relatively strong recovery since then.

Table 4.1

| Year | Enplanements | Deplanements | Transit | | | |

Historical Passengers at ANC

(a) Interpolated from first 10 months.

Sources: Tables C.1, C.2 and C.3.

International enplanements and deplanements at ANC have fluctuated over the past three decades but transit passengers have declined substantially. The main reasons for the decline have been: (1) the introduction of new-generation, long-range aircraft, especially the Boeing 747-400, which has enabled airlines to fly non-stop between Asia and the Lower 48 United States; and (2) the opening of Russian airspace to Asia-Europe flights.

Table 4.2 shows the recent history of passenger enplaning, deplaning, and transit passengers at FAI, and Tables C.4 through C.6 in Appendix C show the same data in more detail. Like ANC, FAI has experienced gradual growth in recent years with a brief decline during the 2008-2009 recession. In contrast to ANC, transit passengers at FAI have increased.

Tables C.7 and C.8 in Appendix C present outbound passenger originations for ANC and FAI organized by intra-AIAS traffic, traffic to other Alaska airports, and traffic to other U.S. airports. The trends over the past twenty years are similar at both ANC and FAI. Originations to Other U.S. (Lower 48 destinations) have grown most quickly, originations between ANC and FAI have grown less quickly, and originations to other Alaska airports have shown the least growth.

Table 4.2

Historical Passengers at FAI

| Year | Enplanements | Deplanements | Transit | | | | |

| 2000-2011 | 0.5% | 0.4% | 4.7% | | | | |
| (a) Interpolated from first 10 months. | | | | | | | |

Sources: Tables C.4, C.5 and C.6.

Domestic Portion of International Journey (DPIJ) passengers are presented in Tables C.9 and C.10. DPIJ counts consist of the domestic leg of an itinerary that includes an international origin or destination. At airports like ANC or FAI, which are not major international passenger gateways, these are essentially international originations passing through another gateway. Note that the growth rates for DPIJs at both ANC and FAI are much greater than the domestic growth rates.

4.2. Historical Air Cargo Activity

This section discusses historical cargo activity at ANC and FAI. For the purpose of this analysis, air freight and air mail have been combined into air cargo. The AIAS airports combine freight and mail into a single category for reporting. In addition, FedEx, which is the single largest mail contractor in the US, reports mail as freight to the US DOT. Consequently, there is no longer an accurate way to distinguish mail from freight. All tonnages in this analysis are presented in short tons (2000 pounds per ton).

Air cargo activity is organized into two main categories, intrastate and other U.S./international. For the purpose of this analysis, non-Alaska U.S. cargo has been combined with international cargo because there is no practical way to separate the two categories. Many U.S. flag carriers commingle international and domestic cargo on the North American leg of their flights. Also, although cargo that clears U.S. Customs in ANC and continues to a U.S. destination is technically domestic, it is international in origin and more subject to the drivers that determine international cargo than domestic cargo.

Intra-Alaska cargo is typically loaded or unloaded at ANC or FAI, includes very little transit cargo, is carried on narrow body jets or turboprops, and has been stable or growing slowly. International cargo is mostly transit, with some transfer activity and very little origin-destination activity (as a percentage of all cargo activity) at ANC or FAI. Virtually all ANC international cargo is carried on large wide body aircraft over long distances and with tight schedule constraints. In addition, international cargo has historically grown faster than any other aviation category at the AIAS airports.

4.2.1. Historical Air Cargo at ANC

Table 4.3 shows historical air cargo tonnage at ANC, with separate totals based on Airport data and US DOT T100 data. Tables C.11 through C.14 in Appendix C provide a more detailed breakout. As noted earlier, airlines have been inconsistent in how they have reported data, so some of the statistics, especially in early years may not be completely accurate. Nevertheless, some trends are evident.

Table 4.3

Historical Total Air Cargo: ANC (Freight and Mail Tons)

| | Enplaned | Deplaned | Transit | Total | | T-100 | |

(a) Enplaned plus deplaned plus transit cargo times 2 (inbound and outbound).

Sources: Tables C.11 through C.14, Anchorage International Airport, Monthly Statistics by Carrier, and HNTB analysis.

First, intra-Alaska air cargo has been stable or declining slowly in recent years. Table C.11 shows intrastate air cargo at ANC as compiled from Airport statistics. Since 1997, trends in intrastate cargo have been similar to intrastate passenger trends with year-to-year fluctuations but no discernible long term trends. Much of intrastate cargo is bypass mail. The bypass mail system allows shippers to deliver pallet loads of at least 1,000 pounds per shipment at a reduced rate directly to an air carrier without transiting a post

office. In this respect, bypass mail is very similar to air freight and is often used by shippers as a substitute for air freight. The costs of the bypass mail system to the United States Postal Service (USPS) far exceed revenue so there have been legislative and regulatory attempts to change (or abolish) the program.

Table C.12 presents air cargo on carriers that ship primarily to and from non-Alaska domestic points. The table shows only a portion of ANC – U.S. flows since much of this traffic is carried by integrated carriers such as FedEx and UPS which commingle domestic and international cargo. Air cargo to the Lower 48 appears to have been declining, but this may be due to a loss in market share to the integrated carriers.

International air cargo reported to the Airport is detailed in Table C.13. U.S. Flag carriers such as FedEx and UPS, which carry mostly international air cargo, are included in this table. Therefore the numbers include some domestic cargo. Very rapid growth rates were evident until 2007. Although much of this growth was real, some may be the result of improved air carrier reporting. Consequently the growth rates are somewhat overstated. International air cargo fell in 2008 and 2009 as a result of the fuel price spike and the recession. Cargo traffic recovered in 2010 but fell again in 2011.

The rapid increase in international air cargo at ANC prior to 2007 is attributable to several factors. First, air cargo has grown rapidly worldwide in recent decades, especially in the Asia-North America market, which according to Boeing grew at a 9.0 percent annual rate between 1981 and 2007. This growth was achieved despite the disruptions of the Asian financial crisis in the late 1990s and the 9/11 terrorist attacks. Because of its strategic location along the great circle routes between Asia and North America, ANC was particularly well-suited to take advantage of this growth. In addition, carriers such as FedEx and UPS were increasingly using ANC as a transfer hub to distribute aircraft payloads better along their North American and Asian routes.

International air cargo at ANC achieved an additional impetus in the late 1990s with the US DOT Alaska Cargo Transfer Initiative, which grants the following privileges to foreign-flag carriers:

- On-line cargo transfers among a foreign flag carrier's aircraft at ANC and FAI;
- Change of gauge operations, provided the aircraft are continuing in the same direction;
- Commingling of U.S. and non-U.S. cargo on the same flight;
- Interline cargo transfers between U.S. and foreign-flag carriers; and
- Interline cargo transfers between different foreign-flag carriers.

The first cargo transfer initiative established ANC as a potential transfer hub for a number of new carriers.

Additional transfer authority was provided as part of the 2003 FAA Reauthorization Bill. Under the legislation, foreign flag carriers were given the right to transfer cargo to other foreign flag carriers at ANC provided the carriers have a code-share agreement, a blocked space agreement, a term arrangement with a U.S. flag carrier operating to or from Alaska, or are carrying cargo on an air carrier waybill of a U.S. flag carrier operating to or from Alaska.

Despite the increases in cargo transfers, ANC's single greatest advantage to air cargo carriers has been its location which allows carriers to maximize their trans-Pacific payloads. Otherwise they would have to sacrifice payload for additional fuel needed to fly non-stop between Asia and North America.

4.2.2. Historical Air Cargo at FAI

Table 4.4 summarizes the available air cargo data at FAI, and Tables C.15 through C.18 provide a more detailed breakdown. In general, air cargo at FAI has declined in recent years with different causes affecting different sectors.

Table C.15 shows the recent history of intra-Alaska cargo to and from FAI. Historically, FAI has been a staging point for air cargo flights to the North Slope. Recently, however, it has lost some of this traffic to airports farther north and therefore experienced a decline in enplaned cargo.

Table C.16 shows FAI air cargo to and from the Lower 48. These flows consist mostly of belly cargo on Alaska, Delta, and Frontier passenger flights.

| | Enplaned | Deplaned | Transit | Total | | T-100 | |

Table 4.4

Historical Total Air Cargo: FAI (Freight and Mail Tons)

Sources: Tables C.15 through C.18.

Until 2005, FAI served as a technical stop for a large number of flights between Europe and Japan/Korea. As long as Russian air space was off-limits to European cargo carriers, FAI enjoyed a significant great circle distance advantage over all other airports, including ANC, on these routes. Once cargo carriers were allowed to overfly Russian airspace, FAI lost the advantage and the traffic.

4.3. Historical Aircraft Operations

This section discusses historical operations at the two AIAS airports and LHD. Multiple data sources were evaluated, including airport landing reports, US DOT T100 data, and FAA Tower statistics. Airport landing reports capture data on all aircraft required to pay a landing fee, i.e., those with a certificated maximum gross takeoff weight of 12,500 pounds or more. US DOT T100 data are filed by commercial aircraft operators such as passenger and cargo carriers. The T100 data also include segment origin and destination data. Unlike other data sources, FAA tower statistics include all aircraft operating at an airport, but at a much lower level of detail. As a result, very detailed data are available for large aircraft, but the data for smaller general aviation aircraft are sparse. An additional issue is the breakout of operations at LHD which the FAA combines with ANC when compiling its statistics.

Table 4.5 presents the recent history of aircraft operations at ANC and LHD. Total annual aircraft operations at ANC gradually declined from 249,677 in 2000 to 211,646 in 2011. The decline resulted from many factors including the loss of international passenger flights, the increase in average size and load factor of domestic passenger flights, and the decline in air taxi, general aviation, and military operations. All-cargo operations increased until 2005, but have since declined.

Information on operations at the Lake Hood seaplane base, located adjacent to ANC, is limited. Until 2007, the Airport analyzed tower counts to provide a breakout of activity between the two airports. LHD operations since 2007 are estimated based on the 2007 breakout of activity. Operations at LHD have declined slightly over the period. In 2010, there were 59,214 air taxi and GA aircraft operations estimated at Lake Hood. ANC and Lake Hood accounted for a combined total of 273,303 aircraft operations in 2010.

US DOT T100 data for 2010 operations are included in the table for comparison purposes. Some operators, such as Alaska Airlines, fly both passenger and all-cargo flights and it is not possible to distinguish between the two types using airport data. Thus the T100 data provide a clearer indication of the distribution of aircraft operations between the categories.

Table 4.6 provides historical aircraft operations data for FAI. Tower statistics on air carrier and air taxi operations are included to provide more detail on activity prior to 2006. Operations at FAI declined from 2000 to 2007, and have since increased. The decline in the early part of the last decade resulted from lost international all-cargo activity and a reduction in general aviation operations. The subsequent increase has resulted from a recovery in general aviation activity and a growth in military operations. In 2011, there were 121,145 operations at FAI, compared to 138,615 operations in 2000.

5.0. Passenger Forecasts

This section presents the assumptions, approach, and results of the passenger activity forecasts for the AIAS airports.

5.1. Passenger Forecast Assumptions

The passenger forecasts are based on several key assumptions that were developed from information collected from the interviews and surveys, discussions with Airport staff, and industry knowledge and publications. This section describes the general passenger forecast assumptions that were applied in this forecast. More detailed assumptions specific to a particular activity category are described in the sections pertaining to those categories. The following forecast assumptions were used in preparing the passenger forecasts:

- No new major economic downturn, such as occurred during the depression of the 1930s or the financial crisis of 2008. Local, national and international economies will periodically increase and decrease the pace of growth in accordance with business cycles. However, it is assumed that over the 20-year forecast term the high-growth and low-growth periods will offset each other so that the adjusted economic forecasts described in Section 2 will be realized.
- The economies of domestic destination markets outside of Alaska will grow in accordance with the W&P CEDDS forecasts which contain projections by metropolitan area for the entire United States. Growth in markets within Alaska will be in accordance with the socioeconomic projections in Section 2.
- Based on ISER's Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035 document, tourism employment will return to 2008 levels by 2014, and grow at 3.0 percent per year thereafter, gradually tapering to 1.5 percent per year. Visitors on cruise ships grew rapidly from the early 1990s through 2007, but fell significantly in 2008 because of the economic downturn and the head tax. Cruise traffic has since experienced a moderate recovery but discussions with industry representatives indicate that the head tax, hotel and attraction capacity, and access constraints will reduce the rate of future growth.
- Fuel prices and average air fares will grow in accordance with the projections in Section 3.
- The Essential Air Service (EAS) program or a similar program will continue to ensure passenger service to rural Alaskan communities. The FAA reauthorization passed in early 2012 retains EAS service to Alaska communities.
- No nighttime curfews at ANC or FAI.
- New environmental regulations and fees will not be so extreme as to significantly constrain air transportation in Alaska.
- An evolutionary expansion of "Open Skies" agreements.
- No passenger or cargo cabotage (transport of origin-destination passengers or cargo between two domestic points by foreign-flag carrier).

- The FAA will successfully implement any required changes and improvements for the national airspace system to accommodate the unconstrained forecast of aviation demand.
- No major international conflicts will disrupt aviation in the North America Pacific area. Likewise, no major trade wars or embargoes will restrict the international flow of commerce and travel.
- Security issues related to air travel will continue to evolve as new procedures and technology enhance airport security. Events that may affect traveler confidence in airport security or air travel security cannot be predicted. It is assumed that there will be no terrorist attacks during the forecast period that will affect confidence in the aviation system to the same extent as 9/11. It is also assumed that the Transportation Security Administration (TSA) and associated security costs and requirements will continue through the forecast period.
- Although some additional airline consolidation could continue to occur, no attempt is made to predict the individual airlines that would be affected.

5.2. Domestic Passenger Forecast

This section describes the domestic passenger forecasts for ANC and FAI including data sources, the methodology for the passenger originations forecast, and the approach used to determine growth by market. This section also includes a discussion of the projections of enplanements and connections, load factors and seat departures. The methodology and assumptions used to estimate the type of air service that would accommodate projected passenger activity are also described.

5.2.1. Methodology and Data Sources

Following is a summary of the bottom-up methodology used in the domestic passenger forecasts for the intra-AIAS, intrastate, and other U.S. markets:

- Identify and project the drivers of passenger activity at the AIAS airports;
- Project future ANC and FAI domestic passenger originations using regression analysis;
- Allocate ANC and FAI originations by market;
- Estimate potential for future non-stop markets based on service thresholds at existing non-stop markets;
- Project future load factors;
- Project future seat departures; and
- Allocate seat departures for each market using the destination market income forecasts.

The methodology will be described in greater detail in subsequent sections of this report.

The following data sources were used in the analysis:

- Historical and projected information on population, employment, and real income by market from Woods & Poole and ISER (see Section 2);
- The US DOT OD1A domestic O&D data base for yield (airline revenue per passenger mile) and distance and historical originating traffic on a market-bymarket basis;
- The US DOT T100 data base to obtain outbound passenger data on a marketby-market basis;
- Official Airline Guide (OAG) information on scheduled operations to determine existing scheduled service and historical non-stop service;
- The OAG, JP Fleet Airline-Fleets International, and individual airline websites to determine aircraft seat configurations for each airline; and
- Airline interviews and surveys, JP Fleet Airline-Fleets International, individual airline websites, and other industry publications to identify information on airline fleet orders.

5.2.2. Domestic Passenger Originations Forecasts

Domestic passenger originations were projected using regression analysis. Regression analysis is a statistical method of generating an equation (or model) which best explains the historical relationship among selected variables, such as originating passengers and real income. If it is assumed that the model that best explains historical activity will continue to hold into the future, this equation can be used as a forecasting tool. Using historical (1990-2009) data, alternative passenger origination forecasting models were tested. The potential driving factors tested included socioeconomic variables, aviation industry variables, and instrument variables (also called dummy variables). The socioeconomic variables included population, employment, income, and per capita income for the Anchorage and Fairbanks MSAs, the State of Alaska, and the United States. The aviation industry variables included ANC and FAI fares to intrastate and other U.S. markets. Instrument variables representing the Gulf War, the 1998 Asian financial crisis, the impact of 9/11, US DOT data collection issues in 2002, and the 2008/2009 financial crisis were also tested in both linear and logarithmic model formulations.

The approach was used to estimate three alternative forecasting equations, one for origin-destination passengers between ANC and FAI, one for originations to the rest of Alaska, and one for originations to the rest of the United States.

Table D.1 in Appendix D presents the forecast equation and originations forecasts for traffic between ANC and FAI. The model that produced the best results, from both a theoretical and statistical standpoint, was a logarithmic formulation which specified per capita originations as a function of combined Anchorage and Fairbanks employment and average air fares between the two markets.

The employment variable represents the size of the market, and the fare variable represents the cost of the service. Since the forecasting model has a logarithmic formulation, each of the exponents associated with the input variables is an elasticity¹. With small changes in the input variables, the forecasting model can be interpreted as indicating that every 1.0 percent increase in employment will increase originations by 0.791 percent and that each 1.0 percent increase in fares will decrease originations by approximately 0.708 percent. Based on the equation and the employment and fare projections O&D traffic between ANC and FAI is projected to increase by about 0.8 percent per year.

Table D.2 in Appendix D presents the originations forecasts to the remainder of Alaska. In this instance, the equation with the strongest statistical results estimated per capita originations as a function of per capita income in the remainder of Alaska and an instrument variable that distinguished ANC from FAI. As shown, originations to the rest of Alaska are projected to increase at 1.2 percent per year for both airports.

Table D.3 in Appendix D presents the originations forecasts to the Lower 48. The equation with the strongest statistical results estimated originations as a function of income in the United States, income in the airport's metropolitan area, average air fares, and an instrument variable that distinguished ANC from FAI. In this forecast, originations are projected to increase 1.3 percent per year for ANC and 1.1 percent per year for FAI. ANC has a slightly higher originations growth rate because income in the Anchorage metropolitan area is projected to grow slightly faster than in the Fairbanks metropolitan area.

Table 5.1 summarizes the domestic originating passenger forecast for ANC and Table 5.2 summarizes the forecast for FAI.

5.2.3. Domestic Outbound Passenger Forecasts

This section presents the forecasts of domestic outbound passengers. Passengers are classified as outbound passengers in the US DOT's T100 data base. They differ slightly from enplanements in that they exclude non-revenue passengers and include outgoing transit passengers. Outbound passengers were projected for the same three categories used for originations. Outbound passengers are the sum of originating passengers, DPIJ passengers, and connecting/transit passengers.

Table D.4 provides the forecast of DPIJ passengers for the two AIAS airports. DPIJs were projected to grow at the same rate as originations with an adjustment for faster international growth based on the relative difference between the FAA's domestic and international passenger enplanement projections.

¹ Elasticity is the ratio of the percentage change of one variable (passengers for example) to the percentage change in another variable (air fares for example). Generally, an elastic variable is one which responds a lot to small changes in other variables. Similarly, an inelastic variable describes one which does not change much in response to changes in other variables.

Sources: Tables D.1, D.2, and D.3

Tables D.5 and D.6 present the forecasts of connecting passengers between ANC and FAI. There are two types of connecting passengers on the ANC-FAI segment, those who connect at ANC and those who connect at FAI. For example, an outbound passenger going from ANC to FAI can be:

- a) A true originating passenger beginning his or her trip at ANC and ending it at FAI;
- b) A passenger who deplanes at ANC from another origin and then boards a flight to FAI (connecting passenger at ANC and terminating passenger at FAI); or
- c) A passenger who originates at ANC and then connects/transits at FAI before continuing to his or her final destination (beyond originating passenger at ANC and connecting passenger at FAI).

Based on historical trends and input from airline surveys, connecting passengers as a percent of total passengers are projected to decline as more airlines offer point-to-point service. The calculations in Tables D.5 and D.6 project these trends to continue, and therefore connecting passengers at both ends of the ANC-FAI segment are projected to decline.

The calculations for the forecast of connecting passengers to other Alaska airports are shown in Tables D.7 and D.8. The source of these passengers is outstate Alaska (the parts of Alaska other than Anchorage or Fairbanks), so it is reasonable to assume that connecting passengers from these points should be related to total passengers at outstate Alaska airports. Therefore, the forecast equation from the Alaska Aviation System Plan Forecasts (published June 2011), updated with more recent socioeconomic forecasts, was used to estimate total outstate Alaska passenger growth. Connections from other Alaska airports, through ANC and FAI, were assumed to increase at the same rate as total outstate passengers.

Table D.9 shows the estimate of passengers from the Lower 48 connecting through ANC or FAI. It is very unlikely that a passenger from the Lower 48 would connect to another point in the Lower 48 through ANC or FAI; therefore it was assumed that all passengers connecting from the Lower 48 would be connecting to an outstate Alaska airport. As shown in Table D.9, intra-Alaska connections were assumed to increase at a rate consistent with internal Alaska growth, namely intrastate Alaska originations, and the remainder were assumed to be connections from outstate Alaska airports to the Lower 48.

The results of the originating passenger, DPIJ, and connecting passenger forecasts were combined to produce forecasts of domestic outbound passengers for ANC and FAI as shown in Tables D.10 and D.11. The forecasts are summarized in Tables 5.3 and 5.4.

Sources: Tables 5.2, D.5, D.6, D.9 and D.11.

As shown, the number of outbound passengers during the forecast period are projected to grow from 2.1 to 2.7 million at ANC, and from 0.5 million to 0.6 million at FAI.

Table 5.4

5.2.4. Seat Departure Forecast

The seat departure forecasts for intra-AIAS, other Alaska, and other U.S. flights were estimated by dividing the outbound passenger forecasts by the projected average load factor in each category. Load factors in each category were assumed to increase at the same rate as the FAA projected domestic load factor. The seat departure calculations for ANC and FAI are shown in Tables D.12 and D.13.

One of the end products of this forecast is a set of detailed future schedules for use in airfield planning and simulation. Market-by-market seat departure forecasts are required to develop the market-by-market operations forecasts for the schedules. Historically, some markets have been increasing their market share of ANC and FAI originations and seat departures at the expense of other markets. In some instances this has resulted from stronger economies, higher population growth or greater tourist interest. Outside of Alaska, Seattle is losing market share to other cities as Alaska Airlines expands its network and new airlines provide additional service to ANC and FAI.

Seat departures to existing non-stop markets were assumed to grow proportionately to originations in those markets, which in turn were projected to grow in proportion to income growth as projected by Woods & Poole. Candidate markets for new non-stop air carrier service were determined by identifying the current thresholds of originating traffic that justified non-stop service to ANC or FAI. Thresholds are lower for nearby markets than more distant markets because service can be offered with smaller aircraft and because there is less competition from connecting hubs between the two markets. In addition, non-stop thresholds are lower for airports that serve as airline hubs because an additional increment of connecting passenger traffic can sustain the service. Originating passengers are projected to grow at most markets during the forecast period. At some of the larger markets without nonstop service, it is expected that this growth would eventually cause originating traffic to exceed the threshold that would result in the introduction of non-stop service.

Using this approach, it was estimated that Newark, Las Vegas, and Spokane would gain new non-stop seasonal service to ANC by the end of the forecast term. Likewise, it was estimated that FAI would gain non-stop service to Portland, Phoenix and Chicago. Should passenger growth be faster than anticipated, the non-stop thresholds for additional markets could be achieved prior to the end of the forecast period. Seat departure projections by non-stop Lower 48 market, including anticipated new markets, are shown in Tables D.14 and D.15.

5.3. International Passenger Forecast

This section discusses the international passenger forecasts for ANC and FAI, including assumptions, methodologies, and results.

5.3.1. Methodology, Assumptions, and Data Sources

The methodology used to develop the international passenger forecasts was essentially a top-down approach. The approach used to estimate domestic passenger traffic was not suitable for the international passenger forecast for several reasons. First, O&D data for passengers flying their entire itinerary on foreign-flag carriers is not available so the historical record is incomplete. Second, many of the international markets are still being developed, so insufficient historical data exist from which to establish trends. Finally, past international service has been constrained or enhanced by physical factors such as distance and aircraft range, and political factors such as bilateral agreements. These constraints tend to obscure the relationship between traditional drivers of demand, such as income and yield, and international passenger traffic.

A top-down approach allows usage of the research and analysis into international travel conducted by the FAA and major aircraft manufacturers such as Boeing and Airbus. These organizations have much greater resources available to investigate and incorporate the factors driving international demand into their forecasts. The selected top-down approach can be summarized as follows:

- Identify forecasts of U.S. international passenger traffic by major region;
- Identify existing international passenger traffic at ANC and determine whether it is enplaning, deplaning, or transit;
- Assess future transit passenger activity based on past trends, distance from origin to destination in existing markets, and developments in aircraft technology;
- Estimate future international outbound and inbound passengers based on international passenger growth rates;
- Develop passenger forecasts by market;
- Estimate future load factors; and
- Project future seat departures by market using the passenger and load factor forecasts.

The methodology will be described in greater detail in subsequent sections of this report.

The following data sources were used in the analysis:

- FAA, Boeing, and Airbus international projections;
- US DOT International Schedule T-100 data base;
- OAG information on scheduled operations to identify existing scheduled service;
- The OAG, individual airline websites, and JP Airline-Fleets International guide to determine aircraft seat configurations for each airline; and
- JP Airline-Fleets International, other industry publications, and individual airline websites to gather information on airline fleet orders.

5.3.2. Forecasts by International Region

Table D.16 in Appendix D presents a comparison of international forecast growth rates developed by the FAA, Boeing, and Airbus. A consensus forecast growth rate was developed for each region using the average of the forecast indexes from the three organizations. Based on the consensus forecast, Asia – North America markets are expected to continue to grow rapidly.

5.3.3. International Transit Passenger Forecasts

Historically, international transit passengers through ANC have been declining as more and more international carriers acquire long-haul aircraft capable of flying from Asia to North America without a technical stop. As of this writing, EVA Airways, flying from Taipei to New York, is the only scheduled international passenger carrier using an AIAS airport (ANC) as a technical stop.

Over the forecast period, it is likely that the introduction of additional long-haul aircraft such as the Boeing 787, coupled with security requirements and competitive pressures from other Asian and U.S. carriers will force EVA Airways to operate its Taipei – New York service non-stop. Therefore, the forecast assumes that all regular international passenger transit service will cease by 2015.

It is anticipated that there will be some residual international transit passenger activity, from charter carriers that generally fly older aircraft with less range and from passengers flying on cargo carriers.

5.3.4. Non-Transit International Passengers

In contrast to international transit passengers, international enplaned and deplaned passengers are projected to continue to increase. Direct (non-transit) passengers in each region were projected to grow at the same rate as the consensus growth rates developed in Table D.16 adjusted to reflect projected economic growth in the Anchorage and Fairbanks metropolitan areas. Forecasts of international outbound passenger forecasts for ANC and FAI are presented in Tables D.17 and D.18.

5.3.5. Seat Departure Forecast

Tables D.19 and D.20 present the international seat departure forecasts for ANC and FAI. Projected seat departures in each region were estimated by dividing the outbound passenger projections by the projected load factor.

5.4. Peak Passenger Activity

Passenger activity at the AIAS airports is very seasonal, and the degree of seasonality differs by category. Intra-Alaska passengers at ANC and FAI are driven mostly by work-related and personal travel peak during the summer but are fairly well distributed

throughout the year. Passenger traffic to the Lower 48 has a strong tourist component, and therefore exhibits a much more pronounced summer peak, with July accounting for about 15 percent of annual enplanements at both ANC and FAI. Seasonality is most pronounced with non-transit international passengers, where August – the peak month for international passengers - accounts for more than a quarter of annual activity at both ANC and FAI.

In addition to seasonal variations, passenger activity varies by day of the week. Seat departures during weekdays are approximately 3 percent above average at ANC and about 6 percent above average at FAI.

An accurate assessment of peaking characteristics is important because airport facility requirements are driven by loads during busy periods (and not annual averages).

Tables D.21 through D.23 present the projected monthly distribution of outbound passengers for each passenger category at ANC. In addition, an estimate of average busy day (weekday) passengers is presented for each month. Table D.24 provides a passenger summary that also includes peak 60-minute passenger enplanements, deplanements, and total movements derived from the design day flight schedules. Tables D.25 through D.28 present the same projections for FAI.

5.5. Passenger Forecast Summary

Tables 5.5 and 5.6 summarize the annual outbound passenger forecasts for ANC and FAI, including domestic and international passengers. As shown, total ANC passengers are projected to increase at about 1.0 percent per year. The growth rate is lower than it would be otherwise because of the loss of the international transit passengers. The average growth rate for FAI outbound passengers is projected to be about 1.2 percent per year.

5.6. Passenger Aircraft Operations Projections

The domestic and international annual seat departure projections developed in earlier parts of this section were translated into projections of scheduled aircraft flights for each market using a set of assumptions regarding airline strategies and available equipment.

5.6.1. Passenger Aircraft Operation Assumptions

The assumptions listed below, are based on interviews and surveys, published aircraft orders, industry publications, and professional experience:

- No radical changes in airline strategy for how to serve and compete in markets. The current pattern of airline dominance at other airport gateways, hubs and nonhubs will remain substantially in place.
- No significant low-cost carrier penetration because of the small size, high operational cost and strong seasonality in Alaska markets.
- As projected by the FAA and Boeing, airlines will continue to emphasize frequency when adding service to meet demand so domestic service will be provided principally by narrow-body aircraft.
- Because of their small size and low growth, little increase in the average size of aircraft serving the smaller intrastate markets.
- Alaska Airlines will continue to use the B-737 family of aircraft as the mainstay of its fleet. Consistent with their published fleet plans, the Boeing 737-800 will be the principal growth aircraft in the near future.
- Smaller Alaska markets will continue to be served primarily by turboprop aircraft, because of the high cost, low cargo capacity, and runway requirements of regional jet aircraft.
- Older aircraft will be gradually phased out as their operational lives expire.
- Airlines' future fleet additions will be consistent with current announced fleet expansion plans and existing acquisitions.
- Over the next 20 years, successors to current narrow-body aircraft such as the Boeing 737 MAX and Airbus A320neo will be introduced. These aircraft are still in the planning and design stage and therefore their technical characteristics are as yet undefined. It is anticipated, however, that they will incorporate many of the innovations developed for the Boeing 787 and Airbus 350XWB.
- As the international air carriers changes from transit to enplaned/deplaned traffic, it is anticipated that they will switch to the smaller wide-body aircraft which are more suited to the anticipated demand for enplaned/deplaned traffic.
- No supersonic, hypersonic, or tilt-rotor aircraft because of poor operating economies and potential noise impacts.

Using the above assumptions for guidance, air service scenarios were developed for each market in each forecast year. The scenarios were developed so that the selected aircraft types and frequencies in combination matched the annual seat departure projections for that market. Factors considered in each market included historical service patterns, current dominant carriers, aircraft in place and on order, length of haul, and announced plans of current carriers and new entrants. The air service scenarios for each market were summarized to generate forecasts of annual aircraft departures and fleet mix.

Passenger aircraft departure projections by aircraft type at ANC for the intrastate, other U.S. and international categories are shown in Tables D.29, D.30, and D.31. Tables D.32, D.33, and D.34 provide the same forecast data for FAI.

5.6.2. Peak Passenger Aircraft Operations

The monthly and weekly distributions of passenger aircraft operations are similar, but somewhat less pronounced, to the distribution for passengers. Tables D.35 through D.38 show projected monthly and average busy day passenger aircraft departures by category for ANC. Tables D.39 through D.42 provide the same forecast data for FAI.

5.6.3. Summary of Passenger Aircraft Operations

Tables 5.7 and 5.8 summarize the annual passenger aircraft departures forecasts for the two AIAS airports. Annual passenger aircraft departures at ANC are projected to increase from 43,265 in 2010 to 50,792 by 2030, an average annual increase of 0.8 percent. At FAI, annual passenger aircraft departures are projected to increase from 18,299 in 2010 to 23,362 by 2030, for an average annual increase of 1.2 percent.

Summary of Annual Passenger Aircraft Departures Forecast Fairbanks

Table 5.8

Sources: Tables D.32, D.33 and D.34.

6.0. Cargo

This section includes a discussion of the forecasts of air cargo demand at the AIAS airports. The survey results and principal assumptions guiding the forecasts are discussed first, followed by descriptions of the intrastate and international air cargo forecasts, and the forecasts of cargo tonnage, all-cargo aircraft operations, and peak activity.

6.1. Survey/Interview Summary

As noted in Section 1.2, the major cargo carriers using the AIAS airports were surveyed and interviewed regarding expected future activity, trends in the industry, and their airport concerns and requirements. Since the vast majority of international and intercontinental operators currently use ANC, most responses pertained to ANC. Survey findings from other studies, such as the Alaska Aviation System Plan study and the previous ANC Master Plan Update are also included when pertinent. Some of the key findings include:

Forecast cargo activity

• Given current cargo demand volatility, the carriers were very reluctant to offer prognostications much beyond the first quarter of 2012, and even those were uncertain.

Intermodal operations

- Most intrastate cargo is transported via ship or road to ANC from which it begins the air portion of its journey.
- No intercontinental intermodal activity currently occurs at ANC or FAI, and none is foreseen.
- ANC and FAI local O&D international freight is a very small component of total air cargo flows for the international carriers.

Forecast aircraft operations

- As with cargo tonnage, forecasts of aircraft operations by type are uncertain.
- Load factors are generally proprietary, but some carriers disclosed numbers in the 90% plus range; in some instances air carriers exceed their capacity by volume before they exceed their capacity by weight which skews load factor data which are traditionally determined by weight.
- A wide range of "peak" months were reported, but generally the traditional fall run-up-to-the-holidays peak season has moderated.
- Frequencies are insufficient to ascertain a meaningful peak hour for each individual carrier (intercontinental hubbing carriers aside).

- For express carriers, westbound flights tend to arrive early in the morning and depart between 9:30 and 11:00 am. Eastbound flights arrive between 11:00 am and 1:30 pm and then depart mid-afternoon.
- Although there is some interest in the freighter version of the Airbus 380, no carriers indicated plans to pursue the aircraft in the near future.
- Some carriers charter aircraft from other countries to circumvent bilateral restrictions.
- Many intrastate carriers rely on large, aging piston and turboprop aircraft that can use the short runways at many of Alaska's smaller airports. There appears to be no viable replacement aircraft of similar size at affordable prices, a source of uncertainty for these carriers.
- Operators of larger aircraft in the intrastate market are closely tied to the North Slope economy.
- Major infrastructure projects such as the proposed Alaska gas pipeline pose a challenge for the cargo carriers in that they would be faced with the prospect of ramping up to achieve short-term gains while later dealing with excess capacity, or abandoning existing customers to take advantage of the new opportunities.
- Significant nighttime operations will continue.

Estimated required parking positions

- Intrastate and intercontinental hubbing carriers have their own ramps that meet their current and foreseen parking position needs.
- Intercontinental gas-and-go (tech. stop) carriers neither need nor expect dedicated parking positions.

Technical stop requirements

- Because of its geographic location, ANC and FAI are ideally suited to allow carriers to maximize Asia North America payload.
- Currently, there are a limited number of westbound overflights from the U.S. west coast to Asia. This may increase in the future with longer range aircraft.
- Carriers expect to continue to need to make technical stops, for refueling and crew changes.
- Some westbound flights overfly Alaska in the summer because of lower payloads but still need an en route stop in winter because of headwinds.
- Carriers sometimes consolidate cargo on westbound flights to reduce load factors on other flights that can then fly non-stop.
- Eastbound cargo operations are extremely time sensitive for express carriers, especially when Daylight Savings Time is in effect in North America (most Asian countries do not use Daylight Savings Time), which narrows the available time window for sort operations.
- Asian airport slots tend to be fixed and therefore impose a constraint on air cargo.

- Deicing is a widespread complaint, specifically cost, service, frequency and ensuing delays.
- Winter weather in general is also a concern because of its impact on schedule integrity.
- There are no substantive Air Traffic Control (ATC) related delays at ANC or FAI.
- Respondents could not conceive of an incentive package that would lure them to FAI, but did not appear to have given much thought to the matter.

Adequacy of current facilities at Alaska International Airports for current and foreseen needs

- The carriers are generally very satisfied with ANC ("it works").
- Some carriers expressed a desire for better deicing capability at ANC.
- Some carriers were especially complimentary about current airport management at ANC and FAI.

6.2. Cargo Forecast Assumptions

The critical assumptions that were used to guide the air cargo forecasts were developed from information collected from the interviews and surveys, discussions with Airport staff, and industry knowledge and publications. They include assumptions on the socioeconomic environment, the political and trade environment, the air cargo industry, technological development, and airport development and operations. As noted in Section 1, the main assumptions were reviewed by the State and key stakeholders.

Key assumptions are as follows:

- No new major economic downturn, such as occurred during the depression of the 1930s or the financial crisis of 2008. Local, national and international economies will periodically increase and decrease the pace of growth, in accordance with business cycles. However, it is assumed that over the 20-year forecast term, the high growth and low growth periods will offset each other so that the adjusted economic forecasts described in Section 2 will be realized.
- The economies of U.S. and Asia/Pacific markets will grow in accordance with the GDP forecasts provided in Table 2.5.
- Fuel prices will increase in accordance with the projections in Section 3.
- No nighttime curfews at ANC or FAI.
- New environmental regulations and fees will not be so extreme as to significantly constrain air transportation in Alaska.
- Although volcanic eruptions are likely to occur in Alaska and elsewhere in the North Pacific, they will cause no long term disruptions in air transportation.
- The Bypass Mail program will continue or be replaced by a similar program that will ensure air cargo access to rural Alaskan communities. Discussions with experts on the issue indicate that although changes are coming to the program, namely increased carrier competition for more efficient service, the Bypass Mail program will continue in some form.

- Cargo Transfer rights at ANC and FAI will continue but there will be no extension of these rights to airports in the Lower 48.
- No passenger or cargo cabotage.
- Cargo operators will continue to place a priority on payload over range to the same degree that they have in the past.
- In the long run, carriers will select technical stops that minimize total distance flown and fuel burn.
- No technological breakthroughs in other transportation modes, such as ocean shipping, that would significantly change the relative costs of alternative modes.
- Russian and Central Asian airports will continue to accommodate the bulk of Europe-Asia technical stops. Since virtually all Europe-Asia cargo now goes non-stop or through Central Asia, Alaskan airports are not at risk to lose any more traffic from this sector.
- The share of Asia-North America freight carried by sea will continue to increase at historical rates. Ocean-borne Asia-North America cargo has been growing faster than air freight, and this is reflected in the historical statistics used to calculate the Asia-North America air cargo flows. As the ocean-borne share grows larger, its rate of increase will decline so that it will never account for 100 percent of the cargo flows.
- The FAA and non-U.S. air traffic control organizations will successfully implement changes and improvements in ATC procedures and technology to accommodate the unconstrained forecast of aviation demand.
- No major international conflicts will disrupt aviation in the North America Pacific region. Likewise, no major trade wars or embargoes will restrict the flow of international commerce and travel.
- Security issues related to air transportation will continue to evolve as new procedures and technology enhance airport security. It is assumed that there will be no terrorist attacks during the forecast period that will affect confidence in the aviation system to the same extent as 9/11. It is also assumed that the Transportation Security Administration (TSA) and associated security costs and requirements will continue through the forecast period.
- TSA cargo inspections will not become as onerous as to drive away tech-stop traffic.
- Although some additional airline consolidation may occur, no attempt is made to predict which individual airlines would be affected.

6.3. Intra-state Cargo Tonnage Forecast

The intra-state cargo tonnage forecast for the AIAS airports is presented in this section. The section begins with an overview of the intrastate market, describes the methodology for projecting cargo tonnage, provides a breakdown of tonnage between all-cargo carriers and passenger carriers (belly cargo) and concludes with an estimate of required aircraft cargo capacity.

6.3.1. Background

Exhibit 6.1 and Table E.1 in Appendix E show the major inbound and outbound intrastate cargo flows at ANC in 2010. Passengers usually fly round trip and therefore outbound passenger counts generally match inbound passenger counts. In contrast, air cargo usually travels one way, resulting in imbalances between inbound and outbound cargo. This is especially true in the intra-Alaska market, where ANC outbound air cargo tonnage is more than threefold inbound air cargo. ANC is a vital lifeline to many small Alaska communities that have no year round access to transportation other than by air. Hence, outbound air cargo flows are very large. These communities export relatively little to ANC and the outside world and therefore inbound cargo flows are much smaller.

As shown in Exhibit 6.1, there has been a slight downward trend in air cargo tonnage over the past seven years. There has been no major change in market share, although over time some communities such as Kotzebue have increased their tonnages to ANC.

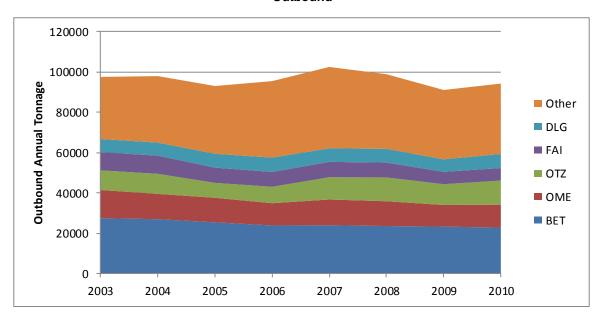

Even though Fairbanks is Alaska's second largest metropolitan area, it ranks only fifth in terms of outbound cargo flows (behind Bethel, Nome, Kotzebue, and Dillingham). Unlike the other communities, Fairbanks has highway access to Anchorage. Therefore, many of the products that would go by air to the less accessible communities can go by truck to Fairbanks. Kodiak is the largest inbound cargo market for ANC, followed by Fairbanks, Kotzebue, and Bethel.

Table E.2 and Exhibit 6.2 show inbound and outbound intra-state air cargo tonnages at FAI, broken out by major market. For FAI, the major outbound market is ANC, followed by Barrow (BRW) and Deadhorse (SCC). ANC is the only inbound market of consequence for FAI, accounting for more than 90 percent of inbound intra-state tonnage.

As shown in Exhibit 6.2, there was a major decline in outbound cargo from FAI between 2005 and 2007, principally because much of the outbound air cargo to Deadhorse now generally moves by truck.

6.3.2. Cargo Tonnage Forecasts

Following is a summary of the methodology used in the intrastate air cargo forecasts:

- Identify and project the drivers of intrastate activity at the AIAS airports;
- Project future ANC and FAI inbound and outbound intrastate cargo using regression analysis;
- Allocate tonnage projections to passenger carriers and all-cargo carriers.
- Project future load factors;
- Project future required air cargo carrier capacity; and
- Allocate cargo capacity for each market.

The methodology will be described in greater detail in subsequent sections of this report.

The following data sources were used in the analysis:

- The US DOT T-100 data base to obtain cargo tonnage and operations data on a market-by-market basis;
- JP Fleet Airline-Fleets International and individual airline websites for aircraft types and configurations for each airline; and
- Airline interviews and surveys, JP Fleet Airline-Fleets International, individual airline websites, and other industry publications for information on airline fleet orders

Table E.3 in Appendix E presents the forecast of air cargo tonnage between ANC and FAI. The forecast equation was estimated using regression analysis (as were the domestic passenger forecasts). The variables that were most statistically significant included the cost of jet fuel, an instrument variable for the 2008-2009 recession, and an instrument variable to distinguish between outbound and inbound cargo.

The results indicate that air cargo flows between ANC and FAI will continue to decline as the price of fuel rises. This is a reasonable result since it is a short haul market that competes with trucking. As the cost of fuel increases, trucks – which burn less fuel per ton-mile - become relatively more cost effective.

Table E.4 in Appendix E shows the forecast of inbound and outbound cargo from the AIAS airports to the remainder of Alaska. Again, regression analysis was used to estimate a forecasting equation for this portion of the market. In this instance, employment in the remainder of Alaska was the most significant variable for outbound cargo, along with an instrument variable to distinguish FAI. Inbound cargo was most closely related to outbound cargo. The equation suggests that at outlying communities, many of which do not have road access, demand is less sensitive to fuel prices and more sensitive to economic factors. Inbound cargo to ANC or FAI from these communities is much less than outbound cargo and probably insufficient to sustain air

service on its own and thus primarily dependent on capacity available on the return flights generated by outbound cargo.

As noted earlier, Alaska's economy is especially dependent on air transportation for the shipment of goods. Since most goods to these communities are already shipped by air, the traditional source of air cargo growth — an increase in market share at the expense of other modes such as truck and rail — is not possible. In addition, the decline in the oil industry will limit increases in demand while, in the long term, the reduced availability of older aircraft traditionally used in intrastate Alaska may constrain service. These factors constrain the growth of intrastate air cargo. However, the continuation of the subsidized bypass mail program will help sustain demand for intrastate air freight.

6.3.3. Belly and Combi- Cargo Tonnage Forecasts

The majority of intrastate air cargo at ANC and FAI is transported by air freight specialists such as Lynden Air Cargo, Northern Air Cargo, Arctic Circle Air Service, and Tatonduk Outfitters. Alaska Airlines, which operates several combi aircraft, is the only passenger carrier that accounts for more than 5 percent of the intrastate cargo market. The national trend has been for the belly cargo share of air freight to decline as integrated carriers have gained market share and passenger carriers have increasingly emphasized quick turnaround times and high passenger load factors, which reduce their ability to transport air freight.

The FAA does not publish a specific cargo load factor forecast. However, the FAA projects passenger Available Seat Miles (ASMs) to increase much faster than Revenue Ton Miles (RTMs) on passenger carriers, it can be inferred that the FAA anticipates passenger carrier cargo load factors will continue to decline relative to passenger load factors. The relationship between FAA-projected RTMs and ASMs was applied to the forecast of domestic seat departures to prepare forecasts of intrastate belly and main-deck combi- cargo for ANC and FAI.

Table E.5 shows the calculation of the belly cargo share of ANC-FAI inbound and outbound cargo tonnage. As shown, total belly and combi- cargo is expected to decline in both directions, consistent with the projected decline in total cargo. Tables E.6 and E.7 show the calculations of the all-cargo and belly cargo split for ANC and FAI to the remainder of Alaska. In those markets, belly and combi- cargo is expected to increase but not as quickly as the all-cargo carrier segment of the market.

6.3.4. Intrastate All Cargo Tonnage and Capacity

Future required all-cargo lift capacity was estimated by dividing outbound all-cargo tonnage by the estimated load factor. Capacity requirements were calculated using outbound cargo since outbound load factors are much higher. Inbound freighter load factors are much lower than outbound load factors and therefore do not materially affect capacity requirements. However, since outbound freighter aircraft ultimately must return to ANC, inbound freighter capacity is equal to outbound capacity.

Projected load factor and required outbound freighter capacity for ANC are presented in Table E.8 in Appendix E. ANC is maintaining cargo load factors in excess of 80 percent to markets in the remainder of Alaska; that is unlikely to go any higher. Meanwhile, cost pressures, especially fuel, will likely cause operators to FAI to reduce capacity until load factors matched those to the rest of Alaska.

Table E.9 shows the calculations for load factor and required outbound freighter capacity for FAI. Outbound capacity from FAI to ANC, i.e., inbound capacity from ANC's perspective, was assumed to change at the same rate as ANC outbound capacity (Table E.9) since air carriers need to complete the return leg of ANC-FAI trips. In this instance, load factor was calculated as a function of cargo tonnage and capacity. The load factor from FAI to the remainder of Alaska was assumed to remain constant.

The capacity requirements were used to estimate intrastate freighter aircraft operations (see Section 6.6 for more detail).

6.3.5. Summary of Intrastate Cargo Tonnage Forecasts

Tables 6.1 and 6.2 summarize the intrastate cargo tonnage forecasts for ANC and FAI. At ANC, combined all-cargo and belly inbound and outbound tonnage is projected to increase from 117,680 tons in 2010 to 137,228 tons in 2030, an average annual increase of 0.8 percent. The belly cargo share is expected to decline slightly and the all-cargo share is expected to increase slightly. At FAI, intrastate cargo is expected to remain roughly constant, with a slight increase in the all-cargo share and a slight decrease in the belly cargo share. FAI intrastate cargo is projected to grow more slowly than ANC intrastate cargo because ANC comprises a very large share of FAI's market, and this particular segment is expected to experience losses to trucking.

Forecast Fairbanks Intrastate Cargo Tonnage Inbound and Outbound (Tons)

Sources: Tables E.3 and E.5.

6.4. International/Other U.S. Cargo Tonnage Forecast

The international and other U.S. cargo tonnage forecast for the AIAS airports is presented in this section. The section begins with an overview of the Asia-North America market, describes the methodology for projecting cargo tonnage, provides a breakdown of tonnage between all-cargo carriers and passenger carriers (belly cargo) and concludes with an estimate of required aircraft cargo capacity.

6.4.1. Background

Prior to discussing the details of the air freight forecasts, it is useful to examine the flow of worldwide air cargo and the role that AIAS airports perform in facilitating that flow. Aircraft carrying air cargo from Asia to North America can take a variety of routings. They can go non-stop, although even the new Boeing 747 or 777 freighters cannot carry enough fuel on most routes without sacrificing payload. Second, aircraft can make technical stops for refueling at intermediate points, such as ANC, FAI or an alternative airport. To save fuel and time, aircraft that do not need to enplane or off-load cargo will usually try to minimize the distance flown. Cargo that is neither loaded nor off-loaded is transit cargo.

Some cargo aircraft currently landing at ANC transfer cargo to and from other aircraft allowing carriers to ship air cargo between Asian and North American markets which generate insufficient traffic to justify a direct route. A transfer operation requires coordinated schedules and adequate on-airport facilities for the transfer operations.

According to the airline surveys a very small amount of enplaned or deplaned air cargo actually begins or ends the air portion of its trip in Alaska. This is considered either originating or terminating air cargo. Air cargo transferred to or from another mode, such as truck or ship, is also counted as originating or terminating air cargo. Some deplaned air cargo is shipped to outlying Alaskan communities, for which air transportation is the only means of access to the outside world. The AIAS airports have little control over air cargo volumes flying between Asia and North America. However, airline routing and operating decisions over the next twenty years, coupled with facility investments made by ANC and competing airports, will determine the share of this air cargo flow that:

- goes non-stop;
- becomes transit cargo at an AIAS airport or a competing airport; or
- is transferred at an AIAS airport or a competing airport.

These factors will largely determine the amount and type of international air cargo activity at ANC and FAI.

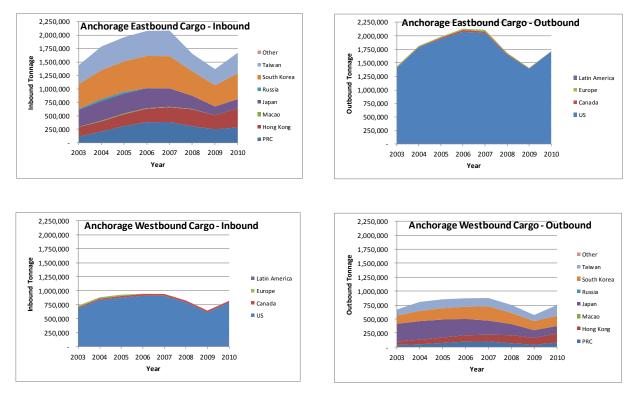

Another characteristic of the Asia-North America market is that it is directionally unbalanced. Asian countries export much more to the United States (measured in both weight and value) than they import. As a result, eastbound cargo tonnage flows – from Asia to North America – are approximately twice westbound flows. Consequently, aircraft flying eastbound tend to have very full (and profitable) loads while they fly light (and unprofitable) loads going westbound. Carriers have adopted a variety of strategies to optimize profitability, including:

- Overflying Alaska to save the time and expense of en route tech stops, since with reduced payload they can carry more fuel;
- Reducing rates on westbound routes to help increase demand; and
- Flying eastbound round-the-world itineraries to avoid the money-losing North America to Asia route.

These factors have had, and will continue to have, an impact on the extent and character of cargo activity at AIAS airports.

Exhibit 6.3 graphically depicts the eastbound and westbound air cargo flows at ANC, broken out by country of flight origin and destination from 2003 through 2010. Since most of the tonnage neither originates nor terminates in Alaska, outbound flows are very similar to the inbound flows on both the eastbound and westbound routes. As shown on the charts, eastbound growth was very rapid until 2007, at which time the fuel price spike, financial crisis and ensuing recession resulted in a major downturn. There was a partial recovery in 2010. Westbound tonnages show a pattern similar to eastbound tonnages, but the upturns and downturns have been less pronounced. South Korea, Taiwan, and Hong Kong are the principal points of origin for the non-stop cargo flows going to ANC. However, in many instances these origins are consolidation points for goods that are manufactured in China or elsewhere in Southeast Asia. The growth in cargo from China and the decline in cargo from Japan is noteworthy. Almost all eastbound cargo is destined for the United States. Westbound destinations are similar to eastbound origins, but the tonnages are less. Again, Japan is showing a significant decline.

Exhibit 6.3

Anchorage International/Other U.S. Air Cargo Flows

Sources: USDOT T-100 database and HNTB analysis.

Table E.10 describes 2010 eastbound air cargo traffic flows at ANC in more detail. This is traffic that originates in Asia, transits or transfers at ANC, and then continues to its final destination, usually to North America but in some cases to Europe. A small amount of this cargo also originates in Asia and terminates in ANC or originates in ANC and terminates in North America or Europe. Outbound cargo flows exceed inbound flows by about 43,000 tons, indicating that cargo originating at ANC or elsewhere in Alaska exceeds Asian cargo terminating at ANC by at least 43,000 tons. The eastbound cargo flows passing through ANC are immense, accounting for over 1.6 million tons in 2010. The primary points of origin (in terms of the non-stop air leg) are Seoul (28.6 percent), Taipei (23.0 percent), Hong Kong (21.3 percent), Shanghai (13.8 percent) and Tokyo (5.7 percent). The primary U.S. destinations are Chicago (22.0 percent), Los Angeles (14.7 percent), and New York (13.7 percent).

Table E.11 shows westbound air cargo traffic flows through ANC in 2010. As noted earlier, westbound flows are slightly less than half of eastbound flows. Air cargo coming from North America to ANC exceeds air cargo going from ANC to Asia by about 67,000 tons, indicating that air cargo originating in North America and terminating at ANC is much greater than air cargo originating at ANC and terminating in Asia. The primary points of origin are Chicago (24.2 percent), New York (14.5 percent), and Louisville (8.7

percent). The chief destinations are Taipei (25.6 percent), Seoul (24.3 percent), Hong Kong (21.9 percent), and Tokyo (11.9 percent).

Exhibit 6.4 depicts eastbound and westbound international and other U.S. cargo tonnages flowing through FAI. FAI's experience has been different than ANC. FAI was principally a technical stop for air cargo operations between Europe and Asia. These diverted to routes across Russia once Russian airspace was opened. Through 2005, eastbound flows were primarily from Japan to Europe and westbound flows were from Europe to Japan. Unlike Asia-North America flows, eastbound and westbound flows were fairly well-balanced. Since 2005, these flows have diminished significantly.

Tables E.12 and E.13 show 2010 eastbound and westbound air cargo flows at FAI. The principal eastbound origins were Nagoya, Japan (49.6 percent), Hong Kong (28.5 percent), and Seoul (11.0 percent) going primarily to Chicago (62.4 percent). Primary westbound origins were Chicago (27.5 percent) and Seattle (18.0 percent) going to Hong Kong (31.6 percent), Seoul (24.0 percent), and Shanghai (20.3 percent).

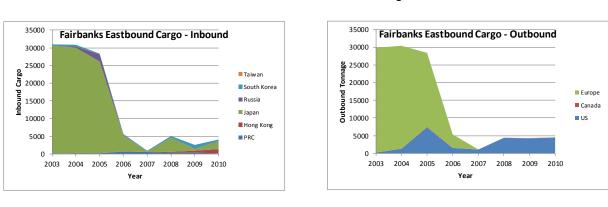

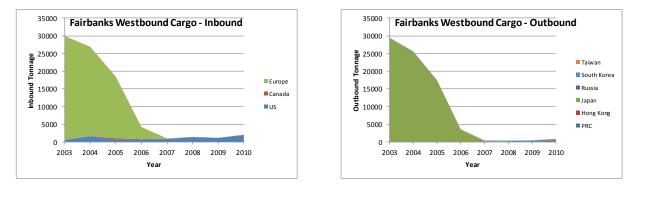

Exhibit 6.4

Fairbanks International/Other U.S. Air Cargo Flows

Sources: USDOT T-100 database and HNTB analysis.

Exhibit 6.5 shows how the AIAS share of eastbound and westbound cargo flows has changed in the recent past. In the exhibit, Other All-Cargo includes both overflights and non-Alaska tech stops. In general, AIAS eastbound and westbound air cargo flows have tracked similarly to total cargo flows but in both cases the AIAS share of traffic has declined slightly.

Table E.14 shows the ANC and FAI shares of total eastbound Asia-North America traffic in 2010. As shown, 67 percent of total eastbound Asia – North America air cargo flows through AIAS airports, including 82.6 percent of all freighter cargo. Only 0.3 percent of belly cargo passes through AIAS airports. There is a direct relationship between distance and Alaska's share of the traffic flow. ANC and FAI account for only 36 percent of the share of air cargo from Japan, but more than 80 percent of the share from Hong Kong and Taiwan.

Table E.15 shows the ANC and FAI shares of westbound North America – Asia traffic. AIAS airports have a smaller share of westbound flows than eastbound flows (58 percent westbound vs. 67 percent eastbound) including 70 percent of all-cargo carrier flows, suggesting that there is more overflying on the westbound legs. Again, AIAS airports have a larger share of traffic to more distant markets such as Hong Kong (88 percent) and Taiwan (73 percent) than closer markets such as Japan (39 percent).

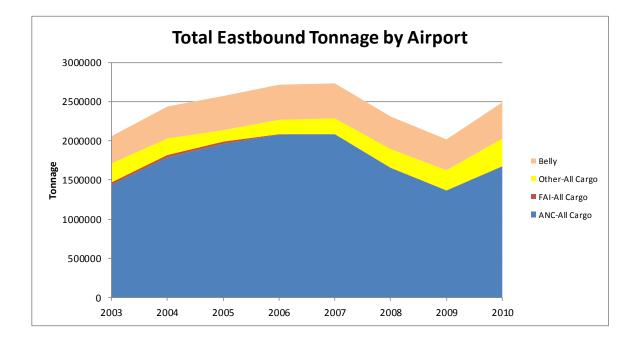

6.4.2. Cargo Tonnage Forecasts

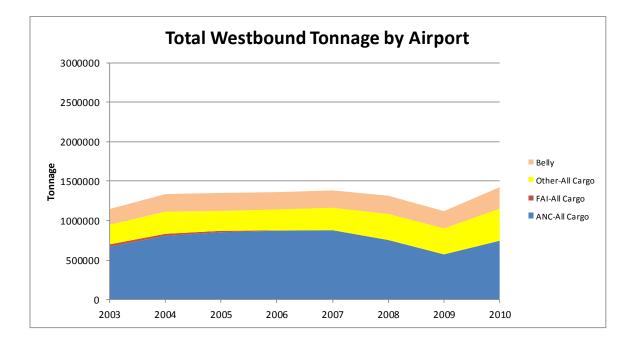

The approach used to project international/other U.S. air cargo involved the following steps:

- Estimate future Asia-North America air cargo flows;
- Estimate the all-cargo carrier share of these flows;
- Identify and assess the factors that affect the share of international air cargo that will pass through the AIAS airports, including imbalances between eastbound and westbound trade flows, location and distance of markets, competition from other potential technical stops, and existing and projected aircraft technical capabilities;
- Project future international westbound and eastbound Asia-North America air cargo tonnage at AIAS airports;
- Estimate the increment of air cargo tonnage on North American legs of eastbound and westbound flows;
- Estimate international and other U.S. belly cargo tonnage;
- Allocate tonnage projections to passenger carriers and all-cargo carriers; and
- Estimate all-cargo aircraft capacity required to serve the international and domestic increments of eastbound and westbound air cargo flows.

Exhibit 6.5

Historical Alaska Share of Eastbound and Westbound Air Cargo Tonnage

Sources: USDOT T-100 database and HNTB analysis.

The data sources were similar to those used for the intrastate forecast and included the Airports, the U.S. DOT's Schedule T-100 statistics, the FAA, Boeing, Airbus, and other industry publications.

For the purposes of this analysis, international air cargo is defined as any shipment whose ultimate origin or destination is outside of the U.S. Therefore, an inbound shipment that arrives from Asia, clears Customs at ANC, and then continues to the lower 48, is still considered international air cargo; even though the shipment is technically domestic freight on the Alaska – Lower 48 segment, it is still subject to the same forces and trends that govern international trade and air cargo.

Since most international cargo at AIAS airports is en route between Asia and North America, it is heavily dependent on air cargo flows between these regions. Table E.16 presents the forecasts of the growth rates in these trade flows calculated as an average of industry forecasts prepared over the past two years by the FAA, aircraft manufacturers such as Boeing and Airbus, and other organizations such as Seabury, OAG, Air Cargo World, and IATA. Collectively, these forecasts project world air cargo to grow at 5.6 percent per year, and Asia/Pacific cargo to grow at 6.8 percent per year.

Many of these forecasts, such as the FAA's, Boeing's, and Airbus' have a history of being overly aggressive. Others do not project far enough into the future or do not provide the level of detail necessary for this analysis. Accordingly, an independent forecast of Asia - North America air cargo tonnage was prepared for this study.

Regression analysis was used to prepare a forecasting equation for eastbound air cargo flows. Since the U.S. DOT T100 data base only began to include all major carriers in 2003, the estimate was prepared on a quarterly basis to include enough observations to generate a sufficiently strong statistical relationship. In addition, some of the variables, such as fuel prices and the financial crisis, showed significant quarterly variation that was masked by annual averages. The variables that were most statistically significant were U.S. GDP, the cost of jet fuel, and instrument variables for the financial crisis, the recession, and seasonal factors.

The GDP and fuel price variables were selected because: (a) they showed a statistical correlation with Asia-North America cargo flows; and (b) historical and projected data were available on a year-by-year basis. Other variables such as commodity composition, value to weight ratios, and individual country exports are undoubtedly also relevant, but the year-by-year historical and forecast detail necessary to include them in the forecast equation is not available. Table E.17 shows the details of the equation and the forecast of eastbound cargo tonnage.

The forecast of total westbound cargo tonnage is presented in Table E.18. In this instance, the most significant variables were East Pacific GDP, jet fuel prices, and instrument variables for the financial crisis and seasonal factors.

The eastbound tonnage forecast projects an average annual increase of 5.4 percent whereas the westbound tonnage forecast projects an average annual increase of 4.4 percent. Given the large imbalance that already exists between eastbound and westbound flows, a further increase in this imbalance was considered untenable. It is likely that cargo carriers would need to raise their rates on eastbound routes to cover their losses on westbound routes and thereby depress eastbound demand. On westbound routes they would likely offer low rates to fill aircraft. Therefore, it was assumed that these two factors would balance out and both eastbound and westbound cargo flows would increase at the average of the calculated rates.

Although full year data for 2011 are not yet available, clearly there has been another downturn in the air cargo market, especially in the Asia-Pacific region. IATA estimates that Asia/Pacific cargo tonnage fell about 6.4 percent between 2010 and 2011. Since Asia/North America cargo flows would be growing from a lower base than originally anticipated, cargo tonnage projections were adjusted to account for this downturn. Table 6.3 shows the forecast of North Pacific air cargo tonnage that reflects both the rebalancing of eastbound and westbound growth rates and an adjustment for the 2011 downturn.

Table 6.3 indicates an average annual growth rate of 4.9 percent, measured from 2011, or 4.3 percent, measured from 2010. The 4.9 percent forecast growth rate for the region is lower than the Boeing and Airbus forecasts. However, given the very slow growth of the last decade and the uncertainty expressed by the cargo survey respondents, it is believed that the 4.9 percent forecast is more realistic.

Using the historical relationship to estimate future Asia/North America air cargo flows assumes that the ocean-borne share will continue to increase as it has in the past, a trend which is reflected in the estimated annual growth rate for air cargo flows.

Table E.19 shows the calculation of total Asia/North America belly cargo. The approach is similar to the approach used to estimate intrastate belly cargo with the exception that FAA projections of international activity are used instead of projections of domestic activity. Passenger carriers flying the Asia-North America routes fly wide-body aircraft, and foreign flag passenger carriers are generally more aggressive in pursuing air cargo than U.S. flag passenger carriers. Therefore, in contrast to domestic belly cargo, international belly cargo is expected to slightly increase its share of total Asia-North American air cargo tonnage.

2011. Growth assumed to resume at projected rates from 2011 base.

(e) Projected tonnage adjusted for 2011 downturn.

Sources: As noted and HNTB analysis.

Tables E.20 and E.21 show total projected eastbound and westbound air cargo flows broken out by country. Tonnage to or from each country was assumed to increase at the same rate as their GDP growth and then adjusted to sum to the total. A close relationship between air cargo tonnage and GDP was already identified from the equations used to estimate North Pacific cargo flows. If no specific GDP forecast was available for an individual country, it was assumed to grow at the same rate as the rest of Asia (excluding China and Japan). The forecasts for each country were adjusted proportionately upwards or downwards to match the total Asia-North America forecast.

The amount of future international cargo that flows through AIAS airports will depend on the need and desirability of ANC or FAI as a technical stop for the carriers engaged in this traffic. In addition to adequate facilities, the desirability of ANC or FAI as a technical stop will depend on four principal factors: (1) shifts in geographic location of demand; (2) potential competition from other technical stops; (3) continued improvements in aircraft technology which will allow longer flights at full payloads; and (4) opportunities for transferring cargo at Alaska (cross-loading) not available elsewhere. Each of these four factors is considered in turn below. China, the fastest growing economy in Asia, is located farther from North America than Japan, Asia's slowest growing economy. Therefore, an increasing percentage of Asia-North America air cargo will need to be transported a greater distance – a factor that would increase the number of flights which require a technical stop.

From a great-circle distance standpoint, Khabarovsk-Novy Airport (KHV) in Russia and Chitose Airport (CTS) in Japan could potentially compete for technical stops on Asia-North America routes. However, it is assumed that environmental concerns and the nighttime curfew will prevent CTS from providing significant competition. It is also assumed that institutional and political concerns will prevent KHV from becoming a major competitor. As the average range of freighter aircraft increases, it is anticipated that Seoul (ICN) in South Korea will be better able to compete for technical stop and transfer traffic between Southeast Asia and the west coast of North America.

The range of freighter aircraft has increased as newer models have become available. The Boeing 747-200F, which has been the mainstay of the long haul freighter fleet, has a range of 3,800 statute miles with a full payload. The MD-11F and 747-400F can fly 4,100 and 5,100 statute miles, respectively, with a full payload. The new Boeing 747-800 will have the same maximum range as the Boeing 747-400 (5,100 statute miles). The standard version of the Boeing 777 freighter has a range of 5,600 miles and the FedEx version has a range of 7,000 statute miles but with a lower maximum payload. The freighter version of the Airbus A380, if built, will have a range of 6,400 miles with maximum payload. Table E.22 in Appendix E shows the range characteristics of long haul freighter aircraft in operation or under development.

Transfer cargo is defined as cargo that is off-loaded from one aircraft and loaded onto another aircraft in Alaska. It is assumed that the air carriers identified as performing significant international cargo transfer activity at AIAS airports will maintain their current market share of Asia-North America cargo tonnage. Based on the air cargo surveys and interviews, three carriers – FedEx, UPS, and Polar for DHL, have significant transfer operations in Alaska. Their share of Alaska non-intrastate tonnage currently accounts for 28% of eastbound tonnage and 30% of westbound tonnage based on U.S. DOT T-100 statistics. It is assumed that these air carriers will continue to handle the same percentage of Asia-North America cargo in Alaska as they did in 2010.

The future AIAS share of technical stop traffic – cargo not being transferred at an AIAS airport – will depend on the interaction of the three previously discussed factors, changes in the geographic origin of traffic, competition from other airports, and increases in aircraft range. To examine these effects, a model was developed to estimate the suitability and competitiveness of AIAS airports as these factors change.

As an input to this model, estimates of the average range of the North Pacific all-cargo carrier fleet were required. In addition to the survey information, data on planned aircraft purchases and retirements were collected for each of the cargo carriers serving the North Pacific cargo market. Purchase and retirement plans extend only for a few years. For the longer term most of the growth is anticipated to consist of Boeing 747-

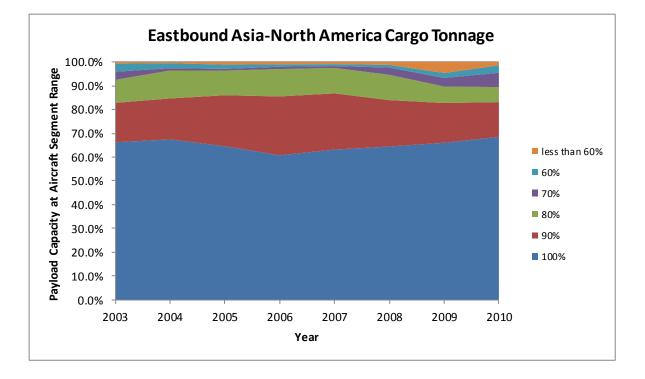

400 passenger conversions, and Boeing 747-8 and 777 freighters. Longer term additional aircraft growth is anticipated from Boeing 777 passenger conversions. By 2030, it is anticipated that freighter variants of the Airbus A350 and A380 will enter service in the North Pacific. Tables E.23 and E.24 show the projected fleet mix for North Pacific cargo carriers over the forecast period and the resulting average range for several different payload scenarios.

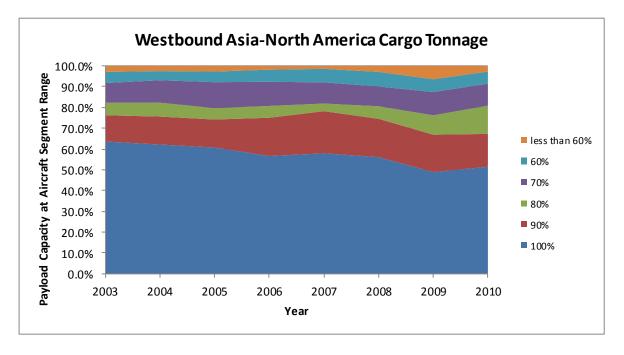

Another factor is the extent to which carriers will trade payload for additional range. Exhibit 6.6 shows the pattern of trade-offs between payload and range in the North Pacific between 2003 and 2010. The graphic shows that on eastbound routes, approximately 70 percent of flights operate on routes where aircraft can carry a full 100 percent payload. More than 80 percent of flights operate on routes where the aircraft can carry at least 90 percent of its maximum payload capacity. Only a small percentage of aircraft operate on routes where they cannot carry more than 60 percent of their maximum payload. On westbound routes, less than 60 percent of flights are flown on routes where aircraft can carry a full 100 percent payload. The westbound graphic suggests that carriers are increasingly taking advantage of the lower loads to do more overflying.

It was assumed that the pattern of trade-offs between range and payload that currently exists among Asia-North America carriers will continue into the future. Based on these data, as of 2010 approximately 35 percent of eastbound Asia-North Pacific air cargo was flown on segments that exceeded the range at maximum payload for the aircraft carrying the cargo. On westbound routes, approximately 43 percent of cargo was flown on segments that exceeded the range at maximum payload for the aircraft.

The assumption essentially states that the percentage of aircraft overflying their range at maximum payload is assumed to remain the same over the forecast period. Since average aircraft range will increase as air carriers transition to a more modern fleet, this will occasion more non-stop flights and more overflying of Alaskan airports. There will be short term fluctuations during the forecast period. During periods of slow economic growth, load factors will likely decline resulting in more flights exceeding range at maximum payload. The reverse will likely occur during periods of rapid economic growth. Exhibit 6.6

Sources: USDOT T-100 database and HNTB analysis.

The Seoul (ICN) to Los Angeles (LAX) route is a good example of the threat of overflying Alaska. The non-stop distance is 5,994 miles (see Table E.25). Based on the data in Table E.23, the average aircraft in the current fleet has a maximum load factor of 80 percent at that range and would therefore need to sacrifice about 20 percent of its eastbound payload capacity to fly ICN-LAX non-stop. Based on the data in Exhibit 6.6, approximately 90 percent of current operators are unwilling to make that trade-off on eastbound routes. By 2030, based on the fleet mix projection in Table E.23, the average aircraft would need to sacrifice less than 10 percent of its payload to fly that route. Again, based on the data in Exhibit 6.6, about 80 percent of operators would still be unwilling to make that trade-off. Therefore, the tonnage on the ICN-LAX route flying non-stop would be expected to double.

As the average aircraft range increases, not only do the opportunities to fly non-stop increase, but the number of potential technical stops, such as ICN, that can be used without sacrificing payload on either segment, also increases. These tradeoffs were calculated for all major market pairs for each forecast year to estimate the amount of technical stop traffic that the AIAS airports can be expected to retain.

Table E.26 presents the estimate of AIAS airports' future share of eastbound North Pacific air cargo tonnage. ANC and FAI currently capture about 77 percent of non-transfer freighter flows between Asia and North America. By 2030, based on the factors enumerated above, this percentage is projected to decline to about 55 percent. As a result, total eastbound cargo flowing through AIAS airports is expected to increase from about 1.7 million tons to 3.1 million tons, an average annual increase of 3.1 percent.

Table E.27 shows the estimate of the AIAS airports' future share of westbound North Pacific air cargo tonnage. ANC and FAI currently capture about 63 percent of non-transfer westbound freighter cargo. By 2030, as average aircraft range increases, this percentage is projected to decline to about 39 percent. Based on this decline in traffic share, AIAS total westbound cargo is expected to increase from 0.7 million tons to 1.3 million tons, an average annual increase of 2.7 percent.

As noted earlier, domestic air cargo traveling between AIAS airports and markets in the Lower 48 is often commingled with international air cargo, especially on U.S. flag carriers. As noted earlier in this section, the North American leg of both eastbound and westbound cargo flows show more tonnage than the Asian leg, and this excess in tonnage provides an estimate of domestic cargo flows between AIAS airports and non-Alaskan U.S. points. The surveys of the cargo carriers serving ANC indicated that there was very little originating or terminating international air cargo at the Airport. Therefore, the additional cargo tonnage on the North American legs of eastbound and westbound cargo flows appear to be a reasonable albeit conservative estimate of domestic air cargo flows between ANC and the Lower 48.

Table E.28 provides a forecast of the additional increment of Alaska – Lower 48 cargo tonnage on the eastbound and westbound legs. Since this traffic is primarily domestic, it was assumed to increase at the same rate as the consensus for domestic cargo

growth from Table E.16. Inbound tonnage is greater than outbound tonnage because many basic commodities not produced in Alaska must be imported from the Lower 48. Most of Alaska's exports to the Lower 48, such as lumber, have high weight to value ratios and are more suitable for waterborne shipping.

Table 6.4 provides the forecast of AIAS international/other U.S. freighter cargo, including the eastbound and westbound international flows combined with the estimated flows to and from the Lower 48 from Table E.28. Also provided is an estimate of the breakout of these tonnages between ANC and FAI. Note that this is a baseline forecast, which does not address either the potential of capacity constraints at ANC, or incentive programs, to divert additional cargo tonnage to FAI.

6.4.3. Belly Cargo Forecast

The freighter cargo projections above were calculated as a share of overall freighter cargo flows between Asia and North America and therefore did not include cargo on passenger carriers. Consistent with the belly cargo assumptions used to estimate the passenger carrier portion of total Asia-North America flows, it was assumed that international belly cargo tonnage would change at the same rate as international passengers. Tables E.29 and E.30 provide the belly cargo forecasts for international and other U.S. cargo for ANC and FAI. Total international belly cargo at ANC is projected to decrease as a result of the anticipated decrease in international transit passengers.

6.4.4. International and Other U.S. All-Cargo Carrier Capacity

Required international air cargo capacity was estimated using the same approach used for intrastate cargo. The projections of freighter tonnage were divided by estimated load factor to arrive at estimates of required lift capacity. Table E.31 in Appendix E shows the required lift capacity calculations for eastbound cargo from Asia to ANC. Because eastbound load factors are already very high, no further increases were assumed. Table E.32 shows the load factor and required lift capacity calculations for westbound cargo from North America to Asia. Based on historical rates, load factors on these routes are projected to increase by almost 1.0 percent per year. Note that these load factor increases do not apply to all North Pacific air cargo flights but rather reflect the air carrier strategies of concentrating westbound cargo on aircraft making a technical stop in Alaska so other aircraft can fly non-stop with very light payloads.

The lift capacity requirements for FAI eastbound and westbound cargo are shown in Tables E.33 and E.34.

6.4.5. International/Other U.S. Air Cargo Summary

Tables 6.5 and 6.6 summarize the total international/other U.S. cargo tonnage forecasts for ANC and FAI. At ANC, combined inbound and outbound all-cargo and belly cargo is expected to grow from 4.9 million tons in 2010 to 8.8 million tons in 2030, an average annual increase of 3.0 percent. At FAI, these tonnages are projected to increase at 3.0 percent per year from 10,954 in 2010 to 19,763 in 2030.

6.5. All-Cargo Aircraft Departure Forecasts

The domestic and international annual cargo capacity projections developed in Tables E.8, E.9, E.31, E.32, E.33 and E.34 were translated into projections of all-cargo aircraft flights for each market using a set of assumptions regarding airline strategies and available equipment. Cargo traffic is much more directional than passenger traffic and therefore there is much less market symmetry between eastbound and westbound flights. For example, the number of all-cargo flights arriving at AIAS airports from Asia is significantly greater than the number of flights departing to Asia. Likewise, the number of all-cargo flights arriving at AIAS airports from Asia is significantly greater than the number of flights departing to Asia. Likewise, the number of all-cargo flights departing to the Lower 48 is significantly less than the number of flights departing to the Lower 48. Consequently, separate estimates were prepared for international aircraft arrivals and departures. Based on the interviews and surveys, published aircraft orders, industry publications, and professional experience, detailed air service assumptions were developed, as listed below:

General All-Cargo Assumptions

- New aircraft types over the forecast period will be based on the fleet acquisition plans of the cargo carriers serving North America, Asia, and Europe.
- There will be no new aircraft with capabilities beyond those currently in the planning or development stages.
- Since the forecast is unconstrained, the fleet mix projections are not limited by the existing number or length of runways or airfield configuration.
- No supersonic, hypersonic, or tilt-rotor aircraft are projected because of poor operating economies.

Intrastate All-Cargo Aircraft Operations

- As they approach the end of their useful economic life, heavy duty piston aircraft most useful for this segment such as the DC-6 and C-46 will be retired. Older 737 aircraft will be used for markets with the runway capability to accommodate them. Smaller turboprops (Dash-8s and Saabs) will be used for markets with shorter runway capabilities.
- Increased numbers of ATR-42 and ATR-72 turboprop aircraft will be introduced into the intrastate cargo market.
- Beech KingAir and QueenAir aircraft will see increased use in the smaller intrastate markets.
- Consistent with Boeing projections and findings from the airline interviews, more Boeing 737 freighters will be introduced as replacement narrow-body air cargo aircraft.

International/Other U.S. All Cargo Aircraft Operations

• 747-100 and -200 will be replaced by Boeing 747-400s.

- Some narrow body and small wide body aircraft will be used to serve the Russian and Canadian markets.
- FedEx, China Southern, and Korean will fly significant numbers of 777 freighters they have on order through ANC.
- Korean, Nippon Cargo, and Atlas/Polar will fly significant numbers of 747-8 freighters they have on order through ANC.
- Carriers with a history of buying Boeing aircraft will add 747-400ERFs and 747-8s to their fleets in the long term.
- Most long term growth will consist of Boeing 747-400 passenger conversions, and new Boeing 747-8 and 777 freighters. Longer-term, additional cargo aircraft growth will be from Boeing 777 passenger conversions.
- By 2030, freighter variants of the Airbus A350 and A380 will enter service.
- Freighter operators will have the financial means to acquire replacement aircraft as their existing aircraft reach the end of their useful economic lives.

Using the above assumptions, air service scenarios were developed for each market in each forecast year. The scenarios were developed so that the selected aircraft types and frequencies in combination matched the annual cargo capacity projections for that market. Factors considered in each market included historical service patterns, current dominant carriers, aircraft in place and on order, length of haul, and announced plans of current carriers and new entrants. The air service scenarios were summarized to generate forecasts of all-cargo aircraft departures, operations and fleet mix.

Tables E.35 and E.36 summarize intra-Alaska all-cargo aircraft departures for ANC and FAI. By the end of the forecast period the ANC intrastate cargo fleet is expected to comprise mostly 737-400s, Cessna 208s, Beech 1900s, and ATRs. At FAI, intrastate all cargo aircraft are projected to include Cessna 208s, Beech 1900s and ATRs.

Tables E.37 and E.38 provide fleet mix projections for international/other U.S. all-cargo aircraft departures at ANC and FAI. The international all-cargo fleet is projected to consist almost entirely of large wide body aircraft, and the Boeing 747-400 is expected to account for the plurality of operations throughout the period. Design Group VI aircraft (Boeing 747-800 and Airbus A380) are forecast to account for about 17 percent of international all-cargo departures at ANC by 2030.

Tables 6.7 and 6.8 summarize all-cargo aircraft departures for ANC and FAI. Total allcargo aircraft departures at ANC are projected to increase from 41,042 in 2010 to 60,598 in 2030, an average annual increase of 2.0 percent. At FAI, all-cargo aircraft departures are projected to increase from 1,659 in 2010 to 2,622 in 2030, an average annual increase of 2.3 percent. Although cargo tonnage is projected to grow faster at ANC than FAI, cargo operations are projected to grow faster at FAI than ANC because of the difference in the fleet mix forecasts for the two airports. At ANC, the average freighter size is expected to gradually increase, resulting in aircraft operations growth less than cargo tonnage growth. At FAI, however, many of the cargo operators use large old piston aircraft to fly to bush markets. The runways at many of these destinations are not capable of accommodating jet aircraft. Therefore, once older piston aircraft such as the DC-6 are cycled out of the fleet they will be replaced by smaller aircraft such as the Embraer 120 or Cessna 208. Consequently, at FAI the average freighter size is projected to gradually decrease, resulting in freighter aircraft operations growing faster than cargo tonnage.

6.6. All-Cargo Peaking Forecast

All-cargo aircraft operations activity at the AIAS airports tends to be less seasonal than passenger activity. Intrastate cargo operations at ANC and FAI have seasonal patterns similar to intrastate passenger operations, i.e., noticeable but not extreme. International cargo operations are fairly well distributed throughout the year but experience a peak in October prior to the holiday season.

In addition to seasonal variations, cargo activity varies by day of the week. Intrastate all-cargo operations are much more frequent during weekdays than weekends. International all-cargo operations have a similar distribution but their operations tend to lag the Asian work week. Therefore, international cargo operations tend to be high from Tuesday through Saturday and low on Sundays and Mondays.

Tables E.39 and E.40 present the projected monthly distribution of all-cargo aircraft operations for each cargo category at ANC. In addition, an estimate of average busy day aircraft departures is presented for each month. Table E.41 provides a summary along with peak 60-minute projections derived from the design day flight schedules. Tables E.42 through E.44 present the same projections for FAI.

7.0. Air Taxi and Other Activity Forecasts

For the purpose of this analysis, the air taxi and other category includes both traditional "for hire" air taxi and also non-commercial charter activity such as the flights operated by BP Exploration and Conoco-Phillips. These operators do not file T100 data with the US DOT and therefore were treated separately from the passenger and air cargo forecasts.

Conoco Phillips shuttle flights to the North Slope account for the majority of air taxi and other passengers at ANC and FAI. Through 2007, this passenger activity varied from year to year but with little discernible long-term trend (see Tables C.1, C.2 and C.3). At ANC this passenger traffic dropped off sharply in 2008, followed by a strong rebound in 2009, 2010 and 2011. These operations serve mainly the intrastate market and are driven mainly by oil and natural gas exploration and development.

Table F.1 in Appendix F shows the ANC forecast of air taxi and other passenger enplanements. The forecast is based on a regression equation in which air taxi and other passengers are a function of crude oil prices, lagged three years. Although oil exploration and development stimulate travel to the North Slope, there appears to be a three year lag before high oil prices stimulate further development. The FAI data were insufficient to develop a regression model, so FAI air taxi and other passenger enplanements were assumed to grow at the same rate as ANC air taxi and other passenger enplanements. This is reasonable since the same operator, Conoco Phillips, accounts for the majority of these passengers at both airports. Tables 7.1 and 7.2 provide the forecasts of enplaned, deplaned, and transit air taxi and other passengers for ANC and FAI.

Tables 7.3 and 7.4 provide the forecasts of air taxi and other aircraft operations for ANC and FAI. Although historical data for these operations are sparse, there appears to have been little change in the aircraft used by this segment in recent years. In addition, there are no published plans for major changes in aircraft types among the air taxi operators at ANC and FAI. Consequently, air taxi and other operations were assumed to increase at the same rate as air taxi and other passengers at ANC and FAI.

A number of the smaller for hire air taxi operations occur at LHD as well as ANC and FAI. Air taxi and other operations at LHD use smaller aircraft and typically support recreational activities such as fishing and hunting expeditions unrelated to oil exploration. These operations were assumed to grow at the same rate as LHD general aviation operations (see Section 8). Table 7.5 provides the forecast of LHD air taxi and other operations.

Table 7 5

Air Taxi and Other Aircraft Operations Forecast

(a) Table 8.1.

(b) Base year operations from Table 4.5. Assumed to increase at same rate as LHD GA operations.

Sources: As noted and HNTB analysis.

Forecast operations by general aircraft type at ANC, FAI, and LHD are shown in Tables F.2, F.3 and F.4 in Appendix F. Base year operations by type were estimated from the FAA's ETMSC data base for instrument operations and from based aircraft counts for non-instrument operations. Operations in each aircraft category were assumed to grow at the same rate as FAA forecast of air taxi and general aviation hours flown in that category. The results were then adjusted on a prorated basis to sum to the original forecast of air taxi and other aircraft operations. In general, jet operations are projected to increase, while other categories are projected to increase more slowly or decrease.

Forecasts of air taxi and other operations by month, average busy day, and peak 60minutes, for each of the three airports are shown in Tables F.5, F.6, and F.7. These operations experience significant seasonal peaks, especially in late summer. The peaking is most extreme at LHD because cold weather conditions limit demand for winter seaplane operations.

8.0. General Aviation Forecasts

General aviation is an important component of aviation in Alaska accounting for 16 percent of operations at ANC, almost 60 percent of operations at FAI, and 76 percent of operations at LHD. Nationally, personal and recreational general aviation has been in decline while corporate and business-related general aviation has been increasing. Both categories suffered declines during the fuel spike and recession of 2008 and 2009, but have experienced a partial recovery in 2010 and 2011.

General aviation at ANC, FAI, and LHD has experienced trends similar to national trends in recent years. Since 2000, general aviation operations have declined at all three airports, but there has been a partial recovery since 2008.

The forecast of general aviation operations at ANC and LHD is presented in Table 8.1. It is based on a market share analysis of U.S. general aviation activity, measured by general aviation hours flown. The change in the historical ratio of ANC/LHD general aviation operations to U.S. general aviation hours flown was calculated, and this change in the ratio was projected to continue in the future. As a share of U.S. general aviation and air taxi hours flown, general aviation operations at these two airports have experienced a slight decline. Since the Anchorage metropolitan area economy is projected to grow less quickly than the U.S. economy in the future (see Section 2) it is reasonable to assume that going forward this decline in share will continue.

Two conflicting factors will affect the future split of general aviation operations between ANC and LHD. The LHD share of general aviation activity has grown over the past ten years, suggesting that the LHD share of general aviation will continue to increase at the expense of ANC. However, jets and sophisticated turboprops represent the fastest growing component of general aviation, and most of these aircraft are unable to use the facilities at LHD suggesting that ANC general aviation will grow faster than LHD general aviation. As a compromise between these countervailing factors, it was assumed that the percentage split between ANC and LHD general aviation operations will remain constant at 2010 levels.

Forecast of General Aviation Aircraft Operations Anchorage and Lake Hood

(a) FAA Aerospace Forecast: FY 2011-2031.

(b) Historical data from Table 4.5. Combined (ANC+LHD) operations estimated by multiplying FAA forecast of hours flown by ratio of (ANC+LHD) operations to hours flown. Split between ANC and LHD assumed to remain constant. See text for additional details.

(c) Ratio of ANC+LHD operations to U.S. Hours Flown. Assumed to change at historical rates.

Sources: As noted and HNTB analysis.

Table 8.2 presents the forecast of general aviation operations at FAI. The forecast approach was the same as that used for ANC and LHD. The historical share of national general aviation activity occurring at FAI has declined slightly faster than the ANC/LHD share and this is reflected in the forecast – a reasonable expectation in that the Fairbanks metropolitan area economy is expected to grow slightly slower than the Anchorage metropolitan area economy. The ANC, FAI, and LHD forecasts are unconstrained, assuming that the airfield, ramp and hangar facilities to accommodate projected general aviation activity will be available. If they are not, general aviation activity will move elsewhere.

Forecast of General Aviation Aircraft Operations Fairbanks

(a) FAA Aerospace Forecast: FY 2011-2031.

(b) Historical data from Table 4.6. Future operations estimated by multiplying FAA forecast of hours flown by ratio of operations to hours flown. See text for additional details.

(c) Ratio of ANC+LHD operations to U.S. Hours Flown. Assumed to change at historical rates.

Sources: As noted and HNTB analysis.

Forecast general aviation operations by aircraft category at ANC, FAI, and LHD are shown in Tables G.1, G.2 and G.3 in Appendix G. Base year operations by type were estimated from the FAA's ETMSC data base for instrument operations and from based aircraft counts for non-instrument operations. Operations in each aircraft category were assumed to grow at the same rate as FAA forecast of air taxi and general aviation hours flown in that category. The results were then adjusted on a prorated basis to sum to the original forecast of general aviation aircraft operations.

Tables G.4, G.5, and G.6 show forecasts of general aviation operations by month, average busy day, and peak 60-minutes for each of the three airports. As with air taxi operations, there is an intense summer peak, especially for LHD and FAI float plane operations.

9.0. **Military Forecasts**

Tables 9.1 and 9.2 present the forecasts of military aircraft operations at ANC and FAI. Military operations at ANC have experienced a significant decline since 2010 as a result of the relocation of the Kulis Air National Guard to Elmendorf Air Force Base completed in February, 2011. Military operations are related to national and international political and institutional factors rather than local economic conditions and are therefore difficult to forecast using traditional approaches. Consequently, military operations are assumed to remain constant at the 2011 level of activity, after an adjustment to net out the impact of Kulis related operations in January of that year.

Military Aircraft Operations

Table 9.1

(a) Historical data from Table 4.5. Assumed to remain constant at 2011 levels with adjustment for departure of Kulis National Guard.

Sources: As noted and HNTB analysis.

The military operations forecast for FAI (Table 9.2) also assumes activity will remain constant at the 2011 level of activity. This assumption is consistent with FAA forecasts of national military activity. However, future national defense actions could increase or decrease future military operations at ANC or FAI.

Military Aircraft Operations Fairbanks

(a) Historical data from Table 4.6. Assumed to remain constant in the future.

Sources: As noted and HNTB analysis.

Forecast military operations by aircraft category at ANC and FAI are shown in Tables H.1 and H.2 in Appendix H. Base year operations by type were estimated from the FAA's ETMSC data base for instrument operations and from based aircraft counts for non-instrument operations. Consistent with the rest of the military operations forecast, operations in each aircraft category were assumed to remain constant.

Tables H.3 and H.4 show forecasts of military aircraft operations by month, average busy day, and peak 60-minutes for ANC and FAI. Summer peaks are evident in this category, but not as pronounced as the peaks associated with general aviation.

10.0. Forecast Summary

This section summarizes the passenger, cargo, and aircraft operations forecasts for ANC, FAI, and LHD. Comparisons with the FAA's Terminal Area Forecast (TAF) are also provided. These baseline forecasts are unconstrained and assume that there will be adequate airfield, terminal, and cargo facilities to accommodate projected traffic. The impact of constraints on aviation activity will be addressed in Section 11.

10.1. Passenger Forecast Summary

Table 10.1 summarizes the demand forecast of annual passenger activity at ANC. The summary includes domestic, international, and air taxi and other passengers, and has been adjusted to match Airport passenger counts that include non-revenue passengers. Total annual enplaned passengers are projected to increase from 2.4 million in 2010 to over 3.1 million by 2030. Consistent with historical trends, total transit passengers are projected to decrease significantly between 2010 and 2030. Combined enplaned and transit passengers, which correspond to outbound passengers in the forecasts in Section 5, are projected to increase 1.0 percent per year during the forecast period.

(a) Assumed to increase at same rate as domestic outbound passengers from Table 5.5.

(b) Assumed to increase at same rate as direct international outbound passengers from Table D.17.

(d) Assumed to increase at same rate as domestic outbound passengers from Table 5.5. Adjusted for downturn in transit passengers in 2011.

(e) Assumed to increase at same rate as transit international outbound passengers from Table D.17.

(f) Air taxi and other included with domestic.

Sources: As noted and HNTB analysis.

Table 10.2 summarizes the passenger forecast for FAI. As with ANC, the projections have been adjusted to match Airport counts of traffic. Compared to ANC, domestic enplanements are projected to grow at a slightly lower rate because of slightly lower anticipated economic growth. On the other hand, international enplanements are projected to grow slightly faster, reflecting a greater mix of overseas and Canadian

⁽c) Table 7.1.

passengers at FAI. Total passenger traffic is projected to grow 1.2 percent per year, slightly faster than ANC since FAI is not expected to experience a sharp reduction in international transit passengers.

Sources: As noted and HNTB analysis.

Tables 10.3 and 10.4 present the forecasts of passenger aircraft landings for ANC and FAI adjusted to reflect airport landing counts. The airport landing counts include some smaller operators that do not file T100 data with the U.S. DOT; further these smaller carriers which operate both passenger and all-cargo flights do not provide a breakdown between passenger and cargo operations. Therefore the distribution of operations between passenger and cargo carriers is slightly different from those presented in Sections 5 and 6.

As shown in Table 10.3, total passenger landings are projected to increase 0.9 percent per year at ANC, slightly less than growth in passenger enplanements. The international growth rate is deceptive because EVA transit flights are included with the cargo landings, and therefore the base numbers are lower than they should be².

Table 10.4 shows the forecast of total passenger aircraft landings for FAI. The domestic landings growth rate at FAI is higher than at ANC because many of the operators fly small aircraft, and have no announced plans to replace them with larger aircraft.

² China Airlines operated transit passenger operations at ANC in 2010, further skewing the base year number, but they have since ceased these operations.

Table 10.3

Summary of ANC Passenger Aircraft Landings Reconciled to Airport Statistics (a)

| Year | Domestic (b) | International (b) | Total |

(b) Accument to increase at some rate on demostic and interpretional.

(b) Assumed to increase at same rate as domestic and international

Sources: As noted and HNTB analysis.

10.2. Cargo Forecast Summary

Tables 10.5 and 10.6 summarize the air cargo tonnage demand forecasts for ANC and FAI. The air cargo projections have been reorganized to correspond to the categories used by the Airport in its accounting: enplaning, deplaning and transit cargo. International/U.S. enplaning and deplaning air cargo tonnage was assumed to increase at the same rate as transfer (cross-loaded) cargo from the forecasts in Table E.26. As shown, total air cargo tonnage at ANC is projected to increase 2.9 percent per year, with most of the increase due to by international air cargo. Total air cargo tonnage at FAI is projected to grow 1.3 percent per year, primarily because international cargo accounts for a smaller share of total FAI freight.

Sources: As noted and HNTB analysis.

The forecasts of cargo aircraft landings for ANC and FAI are presented in Tables 10.7 and 10.8. Total cargo aircraft landings at ANC are projected to increase 2.1 percent per year, less than total cargo tonnage, reflecting an average increase in aircraft size among all-cargo operators. Conversely, cargo landings at FAI are projected to increase at 2.3 percent per year, reflecting the replacement of old aircraft such as the DC-6 by newer smaller turboprops.

10.3. Aircraft Operations Forecast Summary

The demand forecasts of annual aircraft operations at ANC, FAI, and LHD are summarized in Tables 10.9, 10.10, and 10.11.

At ANC, total aircraft operations are projected to increase from 215,564 in 2010 to 281,942 by 2030, an average annual increase of 1.4 percent. All-cargo aircraft operations represent the fastest growing category while military operations show the greatest reduction as a result of the Kulis relocation.

Total aircraft operations at FAI are projected to increase from 121,981 in 2010 to 156,128 in 2030, an average annual increase of 1.2 percent. Like ANC, all-cargo operations are the fastest growing category and military is the slowest growing category.

Summary of Aircraft Operations Forecast Fairbanks

Sources: Tables 5.8, 6.8, 7.4, 8.2, and 9.2.

Table 10.11 summarizes the LHD forecast of aircraft operations. Estimated aircraft operations at Lake Hood are projected to increase from 59,214 in 2010 to 78,348 in 2030, an average annual increase of 1.4 percent.

Tables 10.12 and 10.13 are similar to Tables 10.9 and 10.10 with the exception that the operations forecasts are reconciled to the airports' landing statistics. Since the airport landing reports capture some operators missed by the US DOT T100 data, the effective difference is that some of the air taxi and other operations are reclassified as all-cargo or passenger aircraft operations. Total forecast operations remain the same in both sets of data.

Tables I.1, I.2, and I.3 summarize the peak operations forecasts for ANC, FAI, and LHD. The tables include projected monthly, average busy and peak 60-minute forecasts for total operations at the three airports.

Graphic summaries of passenger enplanement, cargo tonnage, and aircraft operations forecasts for ANC, FAI, and LHD are presented in Exhibits 10.1, 10.2, and 10.3.

10.4. Forecast Comparisons

Table 10.14 compares the ANC AIAS forecast with the TAF. Comparisons are provided for three different categories: passenger enplanements, commercial aircraft operations, and total aircraft operations. The base year TAF ANC enplanement totals are slightly lower than the AIAS totals because the TAF totals exclude non-revenue passengers. The growth rate of the AIAS ANC passenger forecast (1.3 percent) is lower than the TAF growth rate (1.8 percent) and thus the TAF totals are higher by the end of the forecast period. The AIAS growth rate is lower than the TAF growth rate because of more conservative economic growth and fuel cost assumptions. These differences notwithstanding, the two passenger forecasts are very similar and differ by less than 6 percent throughout the forecast period.

The FAA's TAF combines ANC and LHD operations. Therefore, the AIAS forecasts of ANC and LHD operations were combined for the purposes of comparison. Commercial operations include passenger, cargo, and air taxi and other operations. In the TAF, these correspond to the air carrier and air taxi classifications. The AIAS forecast growth rate for commercial operations at ANC (1.4 percent) is lower than the TAF growth rate (1.9 percent) resulting in an AIAS commercial operations forecast that is almost 9.0 percent lower than the TAF by 2030.

Table 10.14

Comparison with FAA Terminal Area Forecast Anchorage and Lake Hood

Sources: Tables 10.1, 10.9 and 10.11, FAA 2011 Terminal Area Forecast and HNTB analysis.

The AIAS and TAF growth rates for total operations at ANC are almost identical - the total operations forecasts in 2030 are within 1.0 percent of each other. The lower AIAS projected growth in commercial operations is offset by higher projected growth in general aviation operations.

Table 10.15 provides a comparison of the AIAS forecast for FAI with the TAF. As shown, the AIAS passenger enplanement forecast is much more conservative (1.2 percent average annual growth rate) than the TAF (2.1 percent average annual growth rate). Again, this is because of the more conservative economic growth and fuel cost assumptions.

The AIAS and TAF commercial operations forecasts for FAI are very similar. As a result, the 2030 projections are within 1.0 percent of each other in this category.

The AIAS forecasts higher total operations growth (1.2 percent per year) than the TAF (0.5 percent per year) primarily because of a higher general aviation aircraft operations forecast. Therefore, by the end of the forecast period, the AIAS operations forecast for FAI exceeds the TAF by more than 14 percent.

According to the FAA, forecasts are considered to be consistent with the TAF if they differ by less than 10 percent within the five-year forecast period, and by less than 15 percent within the ten-year forecast period. The AIAS forecasts for ANC and FAI meet these criteria.

10.5. Conclusion

The above baseline demand forecasts are subject to political, economic and technological factors that are difficult to predict. Therefore, the forecasts should be monitored and compared to actual activity to identify any material deviations. Also, the addition of new airport capacity should be tied to trigger levels to ensure that facilities are phased to come on line when needed and not too soon or too late. Finally, it should be reemphasized that these forecasts represent unconstrained demand. Therefore, if physical, financial, political, or environmental obstacles prevent the implementation of capacity required to accommodate this demand, actual activity levels may be lower than anticipated in these forecasts.

11.0. Forecast Scenarios

The assumptions used in developing the forecasts are likely to vary over the forecast period, and the variations could be material. One way to explore the impact of these variations is to develop alternative scenarios in which the impact on the forecast of a variation in a critical assumption is evaluated. The baseline case forecast provides the basis for determining what additional facilities or policies will be required to manage capacity at the AIAS airports through 2030. The AIAS must be able to respond to a range of contingencies that could occur, taking into account political and economic changes, technological changes, and changes in the policies of individual airlines. The recommended development program must be flexible enough to accommodate these contingencies.

To address these potential changes, seven alternative forecast scenarios were selected with the assistance of DOT&PF staff and the airlines. Much of the background information used to develop the scenarios is provided in previous chapters. The seven scenarios differ from the FAA-approved baseline forecast and include:

- Scenario 1 No-Action
- Scenario 2 High Fuel Price
- Scenario 3 High Economic Growth/Increased International Air Cargo
- Scenario 4 Star Burst
- Scenario 5 Low Fuel Price
- Scenario 6 Updated Base Year
- Scenario 7 Flat Growth

The alternative scenario forecasts for passenger enplanements, cargo tonnage and aircraft operations at ANC, FAI, and LHD are detailed in Appendix L. Tables L.1 through L.8 in the appendix provide the baseline forecasts for comparison.

11.1. Scenario 1 – No Action

The No Action Scenario assumes no airfield, parking, or terminal expansion at ANC, FAI, or LHD, and no policy initiatives to transfer traffic between the two AIAS airports.

Based on the capacity analysis, airlines will begin to adjust operations to manage delay when unconstrained forecast exceeds 258,000 annual operations estimated to occur around 2024. The focus of the analysis was on the afternoon peak (1400-1700) when demand is anticipated to exceed throughput capacity for several hours after 2025. Airlines will react differently to delay, depending on the cost of delay to their operations and their options for managing the delay. The following assumptions were made for individual categories:

- Integrated carrier flights that were at risk of missing a sort (those departing after 1600) were assumed to be redirected to another hub in Northeast Asia or the Western U.S., or to become overflights.
- Tech stop operators during this time period were assumed to overfly Alaska if the payload penalty was minimal. Otherwise, they were assumed to shift operations to FAI to the extent possible with current FAI ramp area.
- Aircraft serving local demand (passenger, intra-state cargo, and GA) were assumed to adjust schedules to minimize operations during the peak period.

Tables L.9 through L.16 present the No Action forecast results. Note that although the annual capacity of ANC is estimated at 258,000 operations, growth can continue afterwards during off-peak periods, but at a slower pace than under the baseline forecast.

11.2. Scenario 2 – High Fuel Price

The High Fuel Price Scenario assumes the U.S. Department of Energy's high fuel price scenario occurs. Under the High Fuel Price Scenario, jet fuel prices would be higher than under the baseline case as shown below:

| Year | Baseline | High |
|------|-------------|-------------|
| 2011 | \$2.94/gal. | \$2.94/gal. |
| 2015 | \$3.23/gal. | \$3.89/gal. |
| 2020 | \$3.66/gal. | \$4.35/gal. |
| 2025 | \$3.98/gal. | \$4.78/gal. |
| 2030 | \$4.19/gal. | \$5.04/gal. |

To remain financially viable, air carriers would need to pass on higher fuel prices through higher air fares and cargo rates, thereby lowering demand.

In addition, based on DOE analysis, each \$10/barrel increase in crude oil prices is assumed to lower Gross Domestic Product (GDP) and income levels by 0.7%.³ This reduced economic growth would also lower demand.

Tables L.17 through L.24 show the combined negative impacts of higher costs of air travel and lower economic growth resulting from the High Fuel Price Scenario.

11.3. Scenario 3 – High Economic Growth/Increased International Air Cargo

The High Economic Growth/Increased International Air Cargo Scenario assumes that the State, U.S., and world economy will grow more rapidly than currently expected. Income and GDP growth rates would correspond to those in the FAA's optimistic

³ U.S. Energy Information Administration, <u>Economic Effects of High Oil Prices</u>, 2006.

economic and aviation activity forecasts as published in the FAA Aerospace Forecast: Fiscal Years 2011-2031. This scenario also uses the average Boeing/Airbus Asia/North America air cargo forecast growth rates as the basis for the international air cargo forecasts, resulting in higher cargo tonnage and operation forecasts for ANC and FAI. Consistent with these forecasts, GDP and income levels are assumed to grow 0.5% per year faster than under the Baseline Forecast after 2012 and total Asia/North America air cargo is assumed to grow at an average of 6.9 percent per year.

As shown in Tables L.25 through L.32, higher economic growth and income levels would significantly increase demand for passenger travel and air cargo.

11.4. Scenario 4 – Starburst

The Starburst Scenario assumes major transfer operations at Alaska international airports resulting in large aircraft coming in from Asia and off-loading cargo to a many smaller aircraft flying to a multitude of North American markets. The scenario assumes that airlines take extensive advantage of the Stevens Act to transfer cargo at ANC. An example would a shipment that currently flies on an aircraft that departs from Shanghai, takes on fuel at ANC, arrives at Chicago O'Hare and is then trucked back to its final destination at Minneapolis. Under this scenario, the shipment would still fly on an aircraft departing from Shanghai and arriving at ANC. However, at ANC the shipment would be transferred to a smaller aircraft flying directly to Minneapolis, thereby eliminating the cost of the truck back-haul.

Specifically, the scenario assumes:

- Integrated carriers such as FedEx and UPS would continue their current operations.
- Carriers accounting for 50 percent of the tech stop cargo would opt to take advantage of the transfer rights at ANC and FAI.
- The fleet mix on Asia-Alaska segments (747/777/MD11) is assumed to be the same as under the Baseline Forecast because of the long distances involved.
- Cargo on Alaska/Lower 48 segments is assumed to be transferred to smaller aircraft (Boeing 757/767). No Boeing 737 classic aircraft are assumed because of their limited range.
- The Scenario assumed to be halfway implemented by 2015, and fully implemented by 2020.

The result would be that less Asia/North America cargo would be lost to overflying than under the Baseline Forecast, and that there would be many more aircraft operations by smaller aircraft. Tables L.33 through L.40 provide the details of this forecast scenario.

11.5. Scenario 5 – Low Fuel Price

The Low Fuel Price Scenario is the reverse of the High Fuel Price Scenario and assumes the U.S. Department of Energy's low fuel price scenario occurs. Under the Low Fuel Price Scenario, jet fuel prices would be lower than under the baseline case as shown below:

| Year | Baseline | Low |
|------|-------------|-------------|
| 2011 | \$2.94/gal. | \$2.94/gal. |
| 2015 | \$3.23/gal. | \$1.60/gal. |
| 2020 | \$3.66/gal. | \$1.58/gal. |
| 2025 | \$3.98/gal. | \$1.55/gal. |
| 2030 | \$4.19/gal. | \$1.55/gal. |

The relationship between oil prices and GDP identified in Scenario 2 is also assumed to apply in this scenario and, therefore, each \$10/barrel decrease in crude oil prices is expected to increase GDP and income levels by 0.7%.

As a result of competition, air carriers are assumed to pass on lower fuel prices through lower air fares and cargo rates. The combination of lower air travel costs and a stronger economy would be expected to significantly increase aviation activity at ANC and FAI. Tables L.41 through L.48 provide the details for this scenario.

11.6. Scenario 6 – Updated Base Year

The updated base year scenario is based on the recognition that current activity, especially air cargo activity, is tracking below interpolated forecast levels. Therefore, this scenario uses the best available estimate of current activity levels and applies the baseline forecast growth rates to the estimated current activity levels. Specifically, the following assumptions are applied in the scenario:

- 2012 annual passenger, cargo and aircraft operation levels were estimated by extrapolating from January September data;
- 2013 levels were assumed to be the same as 2012 because of anticipated constraints on economic growth (U.S. uncertainty on fiscal policy, slowing Asian economies, continuing Euro crisis); and
- Growth was assumed to resume after 2013, at the same rates as in the Baseline Forecast.

When compared to the Baseline Forecast, the Updated Base Year Scenario generates lower projections for ANC, very similar projections for FAI, and higher activity projections for LHD. Tables L.49 through L.56 provide the details for Scenario 6.

11.7. Scenario 7 – Flat Growth

Discussions with the airlines during the review of the forecasts indicated that, in addition to the adverse impacts of the slow economy and high fuel cost, there is an ongoing change in air carrier business models that may further constrain growth. It is too soon to discern the details of these potential business model changes, so a quantifiable analysis of their impacts on the forecast is not possible. As an alternative, a flat growth scenario was developed.

The Flat Growth Scenario uses the Scenario 6 – Updated Base Year assumptions for 2012 and 2013, and then assumes all passenger, cargo and aircraft operations activity remains constant at 2013 levels. Tables L.57 through L.64 provide the details for this scenario.

11.8. Forecast Scenario Comparison

This section provides a comparison of the baseline and scenario forecasts for ANC, FAI, and LHD.

The alternative passenger enplanement forecasts are presented in Tables 11.1, 11.2 and 11.3 and in Exhibit 11.1. The Low Fuel Cost case (Scenario 5) generates the highest enplanement forecast for all three airports, because of the combined impacts of lower travel costs and a stronger economy resulting from the reduced fuel costs. As would be expected, the High Economic Growth forecast (Scenario 3) is also higher than the Baseline case. The Updated Base Year forecast is higher than the Baseline forecast for both FAI and LHD because passenger enplanements have tracked above the forecast between 2010 and 2012.

The High Fuel Cost (Scenario 2) passenger enplanement forecast is lower than the Baseline forecast for all three airports as a result of higher transportation costs and lower economic growth. The Flat Forecast (Scenario 7) is the lowest of all the scenarios for both ANC and FAI. However, for LHD it compares well with the Baseline forecast because of the actual growth that has occurred since 2010.

The Starburst forecast (Scenario 4) is the same as the Baseline forecast because the assumptions for this scenario are not expected to have any measurable impact on passenger enplanements. The No-Action (Scenario 1) enplanement forecast is also the same as the Baseline forecast, because it is expected that passenger carriers would be able to accommodate demand with schedule adjustments through 2030. At some point after 2030, however, the continued growth in passenger demand coupled with no increases in airport capacity at ANC would result in a divergence between the Baseline and No-Action passenger forecasts at ANC.

Updated Base Year

Tables 11.4 and 11.5, and Exhibit 11.2 compare the cargo tonnage forecasts for the Baseline case and the scenarios for ANC and FAI. The High Economic Growth forecast (Scenario 3) shows the highest growth rate for ANC since it also incorporates the aggressive Boeing and Airbus international air cargo projections. The Low Fuel Cost forecast (Scenario 5) is also higher than the Baseline forecast because of lower transport costs coupled with higher economic growth under this scenario. In addition, the Starburst forecast (Scenario 4) is higher than the Baseline forecast (Scenario 1) is the highest of all the scenarios because of the diverted cargo resulting from capacity constraints at ANC.

-Updated Base

-Flat Forecast

Year

Unlike FAI, the No-Action Forecast for ANC is lower than the Baseline because of the increase in overflights and diversions resulting from airfield capacity constraints. The higher transportation costs and lower economic growth resulting from the High Fuel Cost Forecast (Scenario 2) cause this scenario to be lower than the baseline for both ANC and FAI. The Updated Base Year forecast is also lower than the Baseline forecast for both airports because of the downturn in air cargo between 2010 and 2012. Finally, the Flat Forecast is the lowest of all the scenarios because no growth is assumed after the 2010-2012 air cargo downturn.

Aircraft operation forecasts for the Baseline and the seven scenarios are presented in Tables 11.6, 11.7, and 11.8, and in Exhibit 11.3. For ANC, the Starburst forecast (Scenario 4) generates the greatest number of operations since on many routes larger aircraft would be replaced by greater numbers of smaller aircraft. The High Economic Growth (Scenario 3) and Low Fuel Cost (Scenario 5) forecasts of operations are also higher than the Baseline, consistent with the passenger and cargo forecasts. At ANC, the No-Action (Scenario 1), High Fuel Cost (Scenario 2), Updated Base Year (Scenario 6), and Flat Forecast (Scenario 7) are all lower than the Baseline.

With the exception of the No-Action Scenario, all the forecast scenarios are unconstrained. However, Exhibit 11.3 shows that most of the forecast scenarios would reach the ANC airfield capacity constraint (258,000 annual operations) sometime within the forecast period. For the Low Fuel Cost Scenario it would be 2016, for the Starburst Scenario it would be 2018, for the High Economic Growth Scenario it would be 2020, for the High Fuel Cost Scenario it would be 2017, and for the Updated Base Year Scenario it would be 2029. Therefore, with the exception of the Flat Forecast, none of the forecast scenarios could be fully realized without capacity improvements or initiatives to transfer demand from ANC to FAI.

At FAI, the Low Fuel Cost forecast (Scenario 5) would generate the greatest number of operations since GA, which accounts for the majority of operations at the Airport, is very sensitive to fuel prices. In addition, the High Economic Growth forecast (Scenario 3) and No-Action forecast (Scenario 1) would be expected to generate more operations at FAI than the Baseline forecast. Although the effects of the Starburst Scenario would mostly affect ANC, the increased number of operations at ANC would increase the number of unscheduled diversions to FAI, and thereby increase FAI operations slightly. The High Fuel Cost forecast (Scenario 2), Updated Base Year forecast (Scenario 6) and Flat Forecast (Scenario 7) are lower than the Baseline forecast at FAI.

At LHD, the Low Fuel Cost forecast (Scenario 5) generates the greatest number of operations among all the scenarios, followed by the High Economic Growth (Scenario 3) and Updated Base Year (Scenario 6) forecasts. The High Fuel Cost (Scenario 2) and Flat Forecast (Scenario 7) generate the fewest operations.

(a) Table 2,2.

(b) Table 3.3.

(c) Calculated using forecast equation presented below:

ORIG = originations

ORIG = (10^2.277) * (CMEMP^.791) * (FAF^-.708) * REC

where:

CMEMP = Combined Anchorage and Fairbanks metropolitan employmnet.

- FAF = Average fare between ANC and FAI (in 2010 prices).
- REC = Instrument variable equal to (10^-.065) during 2008-2009 recession and 1 in all other years.

| R-squared = .878 | | |
|---------------------|------------|--------|
| Adjusted R-Squar | ed = .867 | |
| F-statistic = 86.04 | | |
| T-statistics | Intercept= | 5.47 |

(a) Table 2.2.

(b) Outbound tonnage estimated using following equation:

AKOUTCGO = (10^-.699) * (AKEMP ^ 1.092) * FAI * REC * TAT2

where:

AKOUTCGO = Outbound cargo tonnage to the rest of Alaska.

AKEMP= Employment in the rest of Alaska

- FAI = Instrument variable equal to (10^-.699) for FAI
- REC = Instrument variable equal to (10^-.0324) during 2008-2009 recession and 1 during other years.
- TAT2 = Instrument variable equal to (10^-.315) during post-2006 reduction in Tatondocs air service and 1 in other years.

Forecast of Alaska Share of North Pacific Air Cargo Flows: Eastbound Inbound

(a) Table E.19.

(b) Alaska share of Eastbound tonnage accounted for by carriers that undertake transfer operations at Alaska (Fedex, UPS and Polar). Assumed to increase at same rate as total tonnage.

(c) Total less tonnage transferred at Alaska.

(d) Total multiplied by Alaska percentage.

(e) Share of non-transfer air cargo assumed to decline as average range of aircraft increases. See text for additional details.

(f) Sum of Alaska transfer and Alaska non-transfer cargo.

Forecast of Air Taxi Passenger Enplanements at ANC

(b) Estimated using following formula:

ATENP = 83085.83 + (693.165*OILLAG) + FIN

where: ATENP = Air Taxi Enplanements
 OILLAG = Average crude oil prices lagged three years.
 FIN = Instrument variable equal to -56530 in 2008 and 0 in all other years.

R-squared = .791 Adjusted R-squared = .739 F-statistic = 15.14 T-statistics: Intercept= 10.87 OILLAG = 3.71 FIN = -5.10

APPENDIX J

FORECAST METHODOLOGY

Appendix J

Technical Memorandum #1:

Final Recommended Methodology for Preparing Aviation Demand Forecast for the AIAS Plan

1. Background and Introduction

The purpose of this memorandum is to describe the proposed aviation demand forecast methodology for the Alaska International Airport System (AIAS) Plan. The AIAS consists of two international airports, Fairbanks International Airport (FAI) and Ted Stevens Anchorage International Airport (ANC) including Lake Hood Airport (LHD). The primary purpose of the AIAS Plan is to provide clear guidance for optimizing the use of AIAS infrastructure, conduct forecasting, and identify capacity constraints and trigger points for capacity improvements. In addition, the planning process will evaluate airport business composition, market conditions, and fiscal challenges, to provide guidance for optimizing AIAS efficiency and opportunity for economic development.

This memorandum presents the methodology to be used in developing aviation demand forecasts for the subject airports. A draft version of this memorandum was submitted to the State, airlines, FAA, and their representatives for review and approval. This final memorandum incorporates the comments that were received.

This technical memorandum will first describe the proposed baseline forecast approach for each of the main activity categories, including air cargo, passenger, air taxi, general aviation, and military. The suggested methodology for preparing the design day flight schedules will then be detailed. Recommended forecast scenarios will then be described. The memorandum will conclude with a detailed description of the deliverables that will be provided as part of the forecast effort, and how they relate to concurrent planning initiatives at ANC, FAI, and LHD.

2. Annual Forecasts

This section provides the recommended processes for forecasting annual activity for air cargo, passenger, air taxi, general aviation, and military activity, including associated aircraft operations.

2.1. Air Cargo Forecasts

For the purposes of the forecast, air cargo will be organized into two main categories, international, and intra-state.

2.1.1. International Air Cargo

International air cargo consists of air cargo which has its origin or destination outside the United States. Most of this cargo originates in Asia, stops in Alaska, and then goes on to the "lower 48". Some of this cargo flows in the reverse direction, originating in the "lower 48", stopping in Alaska, and then going on to Asia. A small portion of this cargo has its ultimate origin or destination within the State of Alaska.

A top down approach is recommended for the forecast of international cargo tonnage. The following steps are envisioned:

- a) Estimate future air cargo flows by region. The focus of this effort will be to estimate Asia-North America flows, although Asia-Europe, Europe-North America, and Asia-South America will also be examined. A statistical regression equation relating regional cargo flows to gross domestic product (GDP) in the United States and Asian countries, along with the price of fuel and variables representing historical disruptive factors such as the financial crisis and natural disasters will be prepared. The results of the regression forecast will be compared with the results of the air carrier survey and forecasts from Boeing, Airbus, the FAA, and other industry experts. The consulting team will then either select a blend of the available forecasts, or choose the forecast that appears most reasonable and defensible as well as seeking guidance from the State's air cargo consultant experts.
- b) Convert cargo flows to tonnages. Most regional cargo forecasts are expressed in revenue ton miles (RTMs) or Revenue Ton Kilometers (RTKs). As the key Asian manufacturing centers have moved from Japan and Korea to China and Southeast Asia, the average length of haul has increased, since the new manufacturing centers are further away from North America. Historical trends in the ratio of RTMs to tonnage will be used to convert the future RTM projections to tonnage projections
- c) Estimate share of cargo moving on passenger aircraft. Industry forecasts of international passenger traffic, especially in the Asia-North America region will be used, in conjunction with an assessment of the future passenger aircraft fleet, to identify the share of international air cargo that would move in the bellies of passenger aircraft. Since virtually all these passenger aircraft are capable of flying non-stop between Asia and North America without a payload penalty, it is unlikely that much of this traffic will use Alaska airports. The share of air cargo moving on all-cargo aircraft will equal total air cargo less the share moving on passenger aircraft.
- d) Estimate share of all-cargo tonnage that would require a technical stop. Based on results of the air carrier surveys, published information on aircraft orders, and

industry forecasts, the aircraft fleet likely to be serving the Pacific region will be assessed. For each of these aircraft types, USDOT T-100 data will be used to calculate the percentage of these aircraft that currently fly routes lengthy enough to incur a payload penalty. It is anticipated that the results will be different for westbound routes which typically have lower load factors, than for eastbound routes. Results from the air carrier surveys will be used to assess whether the share of aircraft flying routes that would incur payload penalties will change in the future. The estimated future fleet mix, in conjunction with the future percentage of aircraft incurring a payload penalty aircraft type, will be evaluated for each major route, to estimate the percentage of all-cargo tonnage that would need a technical stop on each route.

- e) Estimate share of cargo requiring a technical stop that would use Alaska airports. The share of cargo requiring a technical stop will be analyzed to identify the major airports that could serve as a technical stop, based on the criteria that each segment of the route could be served without incurring a payload penalty and minimizing the circuity of the route. This share would represent the future international air cargo tonnage forecast for the Alaska International Airport System.
- f) Distribute cargo between integrated carriers and non-integrated carriers. The results of the airline survey, historical trends, and industry forecasts will be used to allocate Alaska international air cargo between integrated (FedEx, UPS, etc.) and non-integrated carriers.
- g) *Estimate load factor.* The results of the air carrier survey, along with historical trends, will be used to estimate future air cargo load factor. The calculation will be performed separately for eastbound and westbound traffic.
- h) Convert cargo tonnage to aircraft operations by type. The Alaska international all cargo tonnage forecast will be divided by the load factor forecast to estimate required available ton capacity on each route. The available ton capacity will be allocated among airlines and aircraft types for each route while taking the following factors into account:
 - Results of airline survey
 - Current carriers and aircraft serving the route
 - o Individual aircraft tonnage capacity
 - Aircraft on order by carriers

Annual aircraft frequencies on each route will be estimated so that the cumulative cargo capacity of the aircraft estimated for the route will be equal to the required available ton capacity for that route.

i) Prepare baseline allocation of international cargo tonnage and operations among Alaska international airports. The results of the airline survey, the circuity analysis (step e), and current service patterns will be used to provide a baseline allocation of international air cargo activity among the Alaska international airports. The effect of capacity constraints and incentives will be evaluated in subsequent tasks.

2.1.2. Intrastate Air Cargo

Intrastate air cargo consists of air cargo between the two Alaska international airports and the remaining Alaska airport system. Two forecast approaches for intrastate air cargo tonnage will be evaluated, a top-down approach based on a share of U.S. domestic air cargo, and a bottom-up approach based on a regression analysis of local economic and cost factors.

- a) *Top down approach*. The top-down approach can be briefly summarized as follows:
 - o Identify forecast of U.S. domestic air cargo flows (FAA forecast).
 - Calculate the historical change in the Alaska share of U.S. domestic cargo and use that trend to project future changes in share, if any.
 - Apply the future change in share to the FAA domestic forecast of air cargo to identify future AIAS intrastate air cargo tonnage.
- b) Bottom up approach.
 - Prepare a statistical regression equation relating enplaned and deplaned intrastate air cargo at the two AIAS airports to state and metropolitan income and population, fuel costs, and other industry factors.
 - Incorporate economic forecasts from the Institute of Social and Economic Research (ISER) and other organizations, along with fuel cost forecasts from the U.S. Department of Energy into the forecast equation to estimate a bottom-up forecast of intrastate air cargo.

The results of the top-down and bottom-up forecasts will be compared. The consulting team will then either select a blend of the two forecasts, or choose the forecast that appears most reasonable and defensible. Note that local factors are incorporated into the top-down approach, since historical changes in share are usually attributable to differences in relative demand between the local regions and the nation.

The results of the airline survey and current service patterns will be used to provide a baseline allocation of intrastate air cargo activity among the AIAS airports. The effect of capacity constraints and incentives will be evaluated in subsequent tasks.

The passenger fleet mix forecasts will be used to evaluate the future available belly capacity at each of the two airports. Historical trends in passenger carrier cargo load factors will be used to estimate future belly load factors, which will in turn be used to estimate total intrastate belly cargo tonnage. The difference between total intrastate air

cargo tonnage and belly cargo tonnage will be the air cargo tonnage moving on allcargo aircraft.

Future intrastate all-cargo load factors will be estimated separately for inbound and outbound cargo based on historical trends. The intrastate all cargo tonnage forecast will be divided by the load factor forecasts to estimate required available ton capacity on each major intrastate route. The available ton capacity will be allocated among airlines and aircraft types for each route while taking the following factors into account:

- Results of airline survey
- Current carriers and aircraft serving the route
- Individual aircraft tonnage capacity
- Aircraft on order by carriers

Annual aircraft frequencies on each route will be estimated so that the cumulative cargo capacity of the aircraft estimated for the route will be equal to the required available ton capacity for that route.

2.2. Passenger Forecasts

Passenger forecasts will be prepared for two main categories, international and domestic.

2.2.1. International Passenger

International passenger service at Alaska is driven by either transit traffic or origindestination (O&D) demand.

As the range of passenger aircraft has increased, technical stops at Alaska airports by passenger aircraft have declined to near zero operations. Any remaining passenger technical stops will be examined, and the aircraft on order by the incumbent service providers will be examined to determine whether their range characteristics will enable them to overfly Alaska.

Historical international O&D demand at ANC and FAI will be collected and trends in the major markets will be identified to determine whether they will grow sufficiently to warrant new non-stop service to Alaska. Operations and fleet mix associated with international passenger traffic will be based on the existing fleets and fleet plans of the airlines serving existing international markets and those identified as candidates for new non-stop service.

The baseline allocation of international passenger activity among the two AIAS airports will be based on current service patterns and the distribution of O&D traffic among the Anchorage and Fairbanks metropolitan areas.

2.2.2. Domestic Passenger

The domestic passenger category includes passenger traffic going to and from the AIAS airports to domestic points within and outside of Alaska. The following methodology is recommended for the forecasts:

- a) Project future AIAS domestic passenger originations using regression analysis with regional income and average air fares as independent variables. Based on previous experience, different regression equations may be required for intrastate and out-of-state O&D traffic.
- b) Allocate AIAS originations by destination market.
- c) Prepare baseline allocation of AIAS originations among the two AIAS airports based on originating passenger geographic proximity to one of the two airports.
- d) Prepare matrix of potential AIAS connecting passengers. This will show O&D passenger flow between non-AIAS Alaska commercial airports and domestic airports outside of Alaska.
- e) Perform initial allocation of connecting passengers between ANC and FAI based on minimizing circuity time (e.g. which airport serves a given connecting passenger better based on total travel distance).
- f) Screen each U.S. destination market to determine whether combined O&D and connecting traffic is sufficient to sustain non-stop service to either ANC or FAI.
- g) Reallocate connecting traffic among the two AIAS airports if it is determined that one of them cannot support non-stop service to that market based on the screening in the previous step. The reallocation may also be influenced by airline survey results, if they indicate a logistical preference for one of the airports.
- h) The result will be a baseline forecast of O&D and connecting passenger traffic to each AIAS airport broken out by market. The effect of capacity constraints and incentives will be evaluated in subsequent tasks.

A forecast of domestic passenger carrier aircraft operations will be derived from the domestic passenger forecast using the following steps:

- a) Project load factor for each market using FAA growth rates in conjunction with the results of the airline surveys.
- b) Project seat departures for each market by dividing the passenger by the load factor forecasts.
- c) Estimate the most probable manner in which airlines would accommodate the seat departure forecast in terms of aircraft type and frequency of service. The analysis will take into account the results of the airline survey, current carriers and aircraft serving the route, Individual aircraft seat capacity, and aircraft on order by carriers. Annual aircraft frequencies on each route will be estimated so that the cumulative seat departures of the aircraft estimated for the market will be equal to the required seat departures for that market.

2.3. Air Taxi and General Aviation

Air taxi operations consist of for-hire flights that do not fly according to a published schedule. For the purpose of this analysis they will be treated separately from scheduled commuter flights. Since air taxi and general aviation (GA) operations share many characteristics they will be projected using the same general approach. Air taxi and GA forecasts will be prepared for ANC, FAI, and LHD. A key step in the process will be accurately identifying the historical split of operations between ANC and LHD.

As is the case with intrastate air cargo, two forecast approaches be evaluated for GA and air taxi, a top-down approach based on a share of U.S. GA activity, and a bottomup approach based on a regression analysis of local economic and cost factors.

The top-down approach is similar to the approach used for the Alaska Aviation System Plan and can be briefly summarized as follows:

- a) Identify forecast of U.S. GA and air taxi hours flown (FAA forecast).
- b) Calculate the historical change in the Alaska share of U.S. GA and air taxi hours flown and use that trend to project future changes in share, if any.
- c) Apply the future change in share to the FAA forecast of GA and air taxi hours flown to identify future AIAS GA and air taxi activity.

The bottom-up approach would involve the following steps:

- a) Prepare a statistical regression equation relating GA and air taxi operations at ANC, FAI, and LHD to state and metropolitan income and population, fuel costs, and other industry factors.
- b) Incorporate economic forecasts from the Institute of Social and Economic Research (ISER) and other organizations, along with fuel cost forecasts from the U.S. Department of Energy into the forecast equation to estimate a bottom-up forecast of GA and air taxi operations.

The results of the top-down and bottom-up forecasts will be compared. The consulting team will then either select a blend of the two forecasts, or choose the forecast that appears most reasonable and defensible. The effect of capacity constraints and incentives will be evaluated in subsequent tasks.

2.4. Military

The military missions at ANC and FAI will be surveyed to assess any changes in status that may affect military operations at the two AIAS airports. In particular, updated information on the effects of the relocation of the Kulis Air National Guard from ANC to Elmendorf Air Force Base will be requested. That information, in conjunction with FAA forecasts of military activity, will be used to develop an estimate of future military operations at the two AIAS airports.

3. Design Day Flight Schedules

The design day flight schedules will be a key input to the capacity analysis. They will be prepared for an average weekday in the peak month for the base year (2011), 2020 and 2030 for ANC and for the base year (2011) and 2020 for FAI. Note that the base year for the design day flight schedules (2011) will differ from the base year for the annual forecasts (2010). In both instances, the intent is to use the most up-to-date data available. Data from 2010 will be used to calculate the relationships between peak day and annual activity for future design day flight schedules. The flight schedules will include gate/parking position assignment, airline, aircraft type, arrival and departure time, enplaning/deplaning passengers, and originating/terminating passengers. Cargo, passenger, air taxi, GA, and military operations will be included.

The following approaches are recommended for preparing the design day flight schedules:

- An OAG schedule for a weekday in July 2011, coupled with Flight Explorer data and available airport data will be used as the initial source of flight times and operations detail for the 2011 schedules, and for existing flights in the 2020 and 2030 schedules.
- The operations by route forecasts in the cargo analysis and the operations by market forecasts in the passenger analysis will be the sources for flight frequency by airline and aircraft type for each market for the future flight schedules.

Flight times for new flights will be estimated using the following approach:

- Incorporate any input provided in the airline surveys regarding anticipated changes in schedule patterns.
- Avoid wing-tip to wing-tip flying in a given market.
- Schedule take-off and landing times at Alaska to be compatible with hours of operation and curfews at both the origin and destination markets.
- Schedule new flights for integrated cargo carriers to be compatible with the sort operations at their hubs.
- Schedule new flights for passenger carriers to be consistent with their existing connecting bank structure at their hub airports.
- Use existing hourly distribution of operations for air taxi, GA, and military as a guide for estimating new flight times.

Aircraft turnarounds (determination of which arriving flights becomes which departing flight) will be estimated by identifying current turnaround times (by carrier and aircraft type) and using these times as a guide for estimating future turnaround times.

The following assumptions are proposed for assigning parking positions and gates within the design day flight schedules:

- A minimum 15-minute buffer is recommended between an aircraft departure and the next aircraft arrival at each parking position or gate.
- Passenger flights that overnight or have extended dwell times are assumed to be towed off or on their gate as necessary. Assumed dwell times for these aircraft will be 45 minutes for mainline aircraft and 30 minutes for regional aircraft.
- Flights will be initially assigned to parking positions/gates to maximize utilization given the above constraints. Once parking/gate requirements are determined the flights will be redistributed among the required gates to provide for a more balanced operation for the SIMMOD analysis.

4. Scenarios

Up to four forecasts scenarios will be prepared in addition to the baseline forecast. The forecast scenarios will include annual cargo tonnage, annual O&D and connecting passengers, and annual operations by category for the AIAS system, ANC, FAI, and LHD.

Recommended scenarios include:

- a) *No-Action Scenario.* This scenario assumes no airfield, parking, or terminal expansion at ANC, FAI, or LHD. This forecast scenario will be performed after the demand/capacity analysis has been completed.
- b) *High Fuel Price Scenario*. This scenario assumes the U.S. Department of Energy's high fuel price scenario occurs. The impact of higher fuel costs would likely decrease cargo, passenger, and GA activity, and this scenario will estimate the changes in these activity categories for the three airports.
- c) *High Economic Growth Scenario*. This scenario assumes that the State, U.S., and world economy will grow more rapidly than currently expected. Income and GDP growth rates would correspond to those in the FAA's optimistic economic and aviation activity forecasts as published in the <u>FAA Aerospace Forecast</u>: <u>Fiscal Years 2011-2031</u>.
- d) *Increased Aircraft Range Scenario*. This scenario assumes that the next generation of all-cargo aircraft will provide substantial increases in range without incurring payload penalties. The expected result would be more overflying of Alaska and fewer technical stops.

Other potential scenarios could include lower than expected economic growth, disruptions in Asia-North America trade flows resulting from political instability, trade wars, or major volcanic eruptions, changes in the air cargo fleet mix, or changes in integrated carrier sorting practices.

The State DOT&PF will determine the scenarios that are ultimately selected for analysis.

5. Deliverables

The deliverables of this forecast effort are intended to serve the needs of the AIAS study, and the upcoming Master Plan Updates for ANC and FAI, as well as the upcoming Part 150 Study for ANC. The following matrix details the forecast deliverables for 2010, 2015, 2020, and 2030.

| Forecast Item | AIAS | ANC | FAI | LHD |
|--|--------------|--------------|--------------|--------------|
| | System | | | |
| Annual International Cargo Tonnage Forecast | | | V | |
| Annual Intrastate Cargo Tonnage Forecast | | | | |
| Annual Cargo Operations by Airline, Aircraft Type, and Market | V | | \checkmark | |
| Annual International Passenger O&D and Enplanement Forecast by Market | \checkmark | | V | |
| Annual Domestic Passenger O&D and Enplanement Forecast by Market | \checkmark | | V | |
| Annual Passenger Operations by Airline, Aircraft Type, and Market | \checkmark | | \checkmark | |
| Annual Air Taxi Operations by Type | \checkmark | | | \checkmark |
| Annual GA Operations by Type | | \checkmark | | \checkmark |
| Annual Military Operations by Type | | \checkmark | | \checkmark |
| Monthly Distribution of Operations by Category (Cargo, Passenger, etc.) | \checkmark | | \checkmark | \checkmark |
| Monthly Distribution of Passengers | \checkmark | \checkmark | | |
| Average Weekday Peak Month Operations by Category (Cargo, Passenger, etc.) | \checkmark | \checkmark | \checkmark | \checkmark |
| Average Weekday Peak Month Passengers | \checkmark | \checkmark | | |
| Peak Hour Operations by Category | \checkmark | | | \checkmark |
| Peak Hour Passengers | | | | |
| TAF Comparison | | $\sqrt{*}$ | | $\sqrt{*}$ |

*ANC and LHD will be combined for TAF comparison to match FAA accounting practices. The latest available TAF and the FAA comparison tables in "Forecast Aviation Activity by airport will be used in the comparisons.

The following matrix details the forecast information resulting from the design day flight schedules that will be prepared for ANC for 2011, 2020, and 2030 and for FAI for 2011 and 2020. As explained in Section 3, the base year for the design day flight schedule will differ from the base year for the annual forecasts.

| Forecast Item | ANC | FAI |
|--|--------------|--------------|
| Design Day Flight Schedule | | \checkmark |
| Hourly Distribution of Operations by Category | \checkmark | \checkmark |
| Hourly Distribution of Passengers by Category | \checkmark | \checkmark |
| Day/Night/Stage Length Split of Operations by Aircraft | \checkmark | |
| Туре | | |

A detailed technical report will document the assumptions and methodology used for the AIAS forecasts including ANC, FAI, and LHD. The technical report will be complemented by summary reports specific to each airport, which will provide synopses of the approach along with the forecast results pertaining to the airport. The technical report will be made available in electronic form to all interested parties receiving the summary reports.

APPENDIX K

FORECAST ASSUMPTIONS

APPENDIX K

ALASKA INTERNATIONAL AIRPORT SYSTEM PLAN Recommended Forecast Assumptions December 19, 2011

Forecast Assumptions – Purpose

The recommended forecast assumptions will be used as inputs to the aviation forecasts and to provide a context within which the forecasts will be prepared. Some of these assumptions may need to be amended as new information becomes available.

The assumptions were reviewed by the AIAS consulting team, by the airlines, and by representatives of the State, and Anchorage and Fairbanks International Airports and comments and recommendations have been incorporated. The purpose of the assumptions is to provide a reasonable assessment of the key forecast trends and parameters necessary to generate activity forecasts. In many instances, multiple outcomes for these trends and parameters are possible. Therefore, up to four forecast scenarios will be prepared to address the impact of potential variations in these factors.

The input assumptions should not be confused with the aviation activity forecasts. The forecasts will be the output of a process in which input assumptions are incorporated into a methodology/approach that generates the aviation forecast numbers. The assumptions and methodologies used to develop the forecasts will also be documented in the report. The recommended forecast input assumptions are presented below.

Socioeconomic Forecasts

Three sets of socioeconomic forecasts, described in Tables 1, 2, and 3, were considered for use in this study, including:

- Woods & Poole, <u>Complete Economic and Demographic Data Source</u> (CEDDS);
- Alaska Department of Labor and Workforce Development (DOL), <u>Alaska</u> <u>Population Projections: 2010 to 2034;</u> and
- Institute of Social and Economic Research (ISER), <u>Economic and</u> <u>Demographic Projections for Alaska and Greater Anchorage 2010-2035</u>.

Woods & Poole (W&P) is an economic forecasting firm that publishes economic and demographic forecasts for each state, metropolitan area, and county in the United States updated every year. Its advantage is that it is a comprehensive and up-to-date source that provides forecasts for all major economic metrics such as population, employment and income. Its disadvantage is that it does not have the insight into Alaska's conditions that local organizations possess.

(e) Average of Woods & Poole and ISER per capital income projections applied to Alaska Department of Labor Population Projections from Table 1. Rest of Alaska calculated by subtracting Anchorage and Fairbanks MSA totals from State totals.

Sources: As noted and HNTB analysis.

The Alaska Department of Labor's <u>Population Projections</u> are current, having been published earlier in 2011, and reflect in-depth knowledge of the State. The projections, however, are limited to population and do not include employment or income.

The ISER report contains forecasts of population, employment and income for Alaska, the Anchorage Municipality and the Matanuska-Susitna Borough, but includes no information for Fairbanks. Its population forecasts are higher than those prepared by either W&P or the State Department of Labor, but its income forecasts are more conservative than W&P, despite the higher population forecasts.

The State DOL population projections are recommended for use in this study. They are very similar to W&P for the Anchorage and Fairbanks metropolitan areas but appear to better reflect the ongoing out-migration in more rural parts of Alaska.

For employment projections, a hybrid approach that applies the per capita employment projections from the W&P forecasts to the State DOL population projections is recommended. This approach helps maintain consistency with the population projections, especially with respect to the relative growth rates between Anchorage, Fairbanks and the remainder of Alaska.

A similar hybrid approach is recommended for income. This involves applying the average of the ISER and W&P per capita income projections to the State DOL population projections. The W&P income projections were considered too aggressive by regional economic development experts familiar with Alaska. The ISER projections, on the other hand, have a history of being conservative. Therefore, taking the average of the two forecasts is considered a reasonable compromise.

There are some concerns that using a 2009/2010 base year during the middle of an economic downturn may bias the projections in a negative way. However, the large amount of public debt and anticipated reductions in government spending will likely reduce the rate of future economic growth, so the period of rapid recovery experienced in other business cycles is less likely to occur this time.

The W&P CEDDS forecasts, which contain projections by metropolitan area for the entire United States, are recommended for use in distributing the market-bymarket passenger forecasts for the remainder of the United States.

Global Insight forecasts of Gross Domestic Product (GDP) by world region, as published in the FAA Aerospace Forecasts: FY 2010-2031, as shown in Table 4 are recommended for use in the international forecasts. They are the most recent available forecasts that cover all the regions in question.

GDP Forecast by Region (millions of 2005 US Dollars)

Source: Global Insight, as published in FAA Aerospace Forecasts: 2011-2031, March 2011.

Fuel and Other Air Carrier Operating Costs

Jet fuel prices are an important determinant of aviation demand and will be incorporated in both the passenger and cargo forecasts. Jet fuel prices are very sensitive to crude oil prices which have extremely volatile over the past several years. Several forecasts of jet fuel and crude oil prices were considered (see Table 5). Actual jet fuel prices (through September 2011) are shown for comparison.

The United States Department of Energy (DOE) provides specific forecasts on jet fuel prices, but most other sources provide forecasts of crude oil prices only. In general, the DOE projects oil and jet fuel prices to increase gradually in their Reference case and much more rapidly in their High Oil Price scenario. The FAA's estimate of crude prices anticipates a gradual increase through 2015 and then a decline. In their forecast for Anchorage and Alaska, ISER assumed a cost of \$95.00 per barrel in 2009 prices (\$96.69 in 2010 prices) throughout the forecast period. As of this writing, crude oil and jet fuel prices have been tracking higher than most forecasts had indicated. As of September 2011, actual jet fuel prices were close to the DOE high forecast, whereas as of November 11, 2011, spot crude oil prices were \$98.18 per barrel, higher than the FAA or base DOE forecasts and close to the ISER forecasts.

(f).S. Department of Energy, Annual Energy Outlook 2011, Reference Case.

(g) Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035, by Institute of Social and Economic Research and Northern Economics, December 2009. Converted to 2010 prices.

Sources: As noted and HNTB analysis.

The recommended fuel price forecast assumes that fuel prices grow gradually in real terms to the average of the DOE Reference and High forecasts to 2015, and then continues to grow at the average of the DOE Reference and High cases thereafter. This assumption incorporates the continuing tendency of fuel prices to track higher than most forecasts but does not completely accept the DOE High forecast, which was intended to represent an extreme case.

Fuel Availability

It is assumed that ANC, FAI, and the airlines will continue to take whatever measures are necessary and install whatever facilities are required to avoid the fuel availability issues of the past and to ensure that jet fuel is available to the carriers at market rates.

The possibility that fuel availability may constrain growth in airport activity and the measures that ANC and FAI can take to ensure fuel availability, will be addressed in more detail during the incentives study as part of the strategic plan that will be undertaken after the forecast.

Asia/North America Air Cargo Flows

Based on an econometric forecast equation relating Asia/North America air cargo flows from the U.S. DOT's T100 data base to regional GDP and fuel prices it is estimated that total Asia/North America air cargo flows (going through Alaska, through other airports, or nonstop) will increase at an average of 4.9 percent per year. This growth rate assumes the recommended GDP and fuel price forecasts (Tables 4 and 5). If GDP is higher than the recommended forecast the Asia/North America air cargo flow forecast will also be higher. If fuel prices are higher than the recommended forecast, the Asia/North America air cargo flow forecast will be lower. The analysis is focused on Eastbound and Westbound trans-continental cargo flows, so it is not affected by domestic/international cargo designations which can vary by carrier and data source.

The GDP and fuel price variables were selected because a) they showed a statistical correlation with Asia/North America cargo flows and b) historical and projected data were available on a year-by-year basis. Other variables such as commodity composition, value to weight rations, and individual country exports are no doubt also relevant, but the year-by-year historical and forecast detail necessary to include them in the forecast equation is not available.

The 4.9 percent forecast growth rate for the region is lower than the forecasts published by Boeing or Airbus. However, given the very slow growth of the last decade and the uncertainty expressed by the cargo survey respondents, it is believed that the 4.9 percent forecast is more realistic.

Note that a 4.9 percent growth in Asia/North America trade flows will not automatically translate to 4.9 percent growth for the Alaska international airports. The share of this traffic growth captured by Alaska airports will depend on the degree of overflying and diversion to other airports.

Competition from Ocean-Borne Freight

It is assumed that the share of Asia-North America freight carried by sea will continue to increase at historical rates. The ocean-borne share of Asia/North America cargo has been growing faster than the air carrier share, and this is reflected in the historical statistics used to calculate the Asia/North America air cargo flows. Using the historical relationship to estimate future Asia/North America air cargo flows implicitly assumes that the ocean-borne share will continue to increase as it has in the past. This is reflected in the 4.9 percent estimated annual growth rate for air cargo flows. As the ocean-borne share grows larger, its rate of increase will decline so that it will never account for 100 percent of the cargo flows

Competition from Belly Cargo

Newer passenger aircraft such as the Boeing 777-300 have substantial belly cargo capacity. The FAA accounts for this in their national forecast by projecting international belly cargo to grow at a faster rate than international passengers. This factor will be incorporated into the forecast, resulting in a slight loss of future market share from all-cargo carriers to passenger carriers on Asia/North America flights.

Range/Payload Trade-Off

It is assumed that the pattern of trade-offs between range and payload that currently exists among Asia/North America carriers will continue into the future. Based on an analysis of USDOT T100 data, as of 2010 approximately 35 percent of Eastbound Asia/North Pacific air cargo was flown on segments that exceeded the range at maximum payload for the aircraft carrying the cargo. On Westbound routes, approximately 43 percent of cargo was flown on segments that exceeded the range at maximum payload for the aircraft.

The assumption essentially states that the percentage of aircraft overflying their range at maximum payload is assumed to remain the same over the forecast period. Since average aircraft range will increase as air carriers transition to a more modern fleet, this will mean more non-stop flights and more overflying of Alaska airports.

There will be short-term fluctuations during the forecast period. During periods of slow economic growth, load factors will likely decline resulting in more flights exceeding range at maximum payload. The reverse will likely occur during periods of rapid economic growth.

Transfer Cargo

Transfer cargo is defined as cargo that is off-loaded from one aircraft and loaded onto another aircraft in Alaska. It is assumed that the air carriers identified as performing significant international cargo transfer activity at Alaska international airports will maintain their current market share of Asia/North America cargo tonnage. Based on the air cargo surveys and interviews, three carriers – FedEx, UPS, and Polar for DHL, were identified as having significant transfer operations in Alaska. Their share of Alaska non-intrastate tonnage accounts for 28% of eastbound tonnage and 30% of westbound tonnage based on USDOT T-100 statistics. It is assumed that these air carriers will continue to process the same percentage of their Asia/North America cargo at Alaska as they did in 2010.

Future Regulatory Environment

Recommended regulatory assumptions are as follows:

- Evolutionary expansion of "Open Skies" agreements
- Continuation of Cargo Transfer rights at ANC and FAI but no extension of these rights to airports in the "Lower 48."
- No passenger or cargo cabotage
- Continuation of the Bypass Mail program in its current form or a similar program that will ensure air cargo access to out-state communities in Alaska. Discussions with experts on the issue indicate that although changes are coming to the program, namely increased carrier competition for more efficient service, the Bypass Mail program will continue in some form.
- Continuation of the Essential Air Service (EAS) program or similar program that will ensure passenger service to out-state communities in Alaska. Current versions of the proposed changes to the EAS program retain service to Alaska communities.
- No nighttime curfews at ANC or FAI.
- New environmental regulations and fees will not be so extreme as to significantly constrain air transportation at Alaska.
- TSA cargo inspections won't become as onerous as to drive away techstop traffic.

Growth in Tourism and Cruise Industry

Visitors on cruise ships grew rapidly from the early 1990s through 2007, but fell significantly in 2008 because of the economic downturn and the head tax. Cruise traffic has since undergone a moderate recovery but discussions with industry representatives indicate that the head tax, hotel and attraction capacity, and access constraints will reduce the rate of growth in the future. ISER projects that tourism employment will return to 2008 levels by 2014, and grow at 3.0 percent per year thereafter, gradually tapering to 1.5 percent per year, in their Economic and Demographic Projections for Alaska and Greater Anchorage 2010-2035 document

Long-Term Developments in Aircraft Design

Aircraft fleet projections will rely heavily on the air carrier survey results and published aircraft orders. The following general assumptions are recommended for use where necessary:

• *Mainline passenger aircraft*. Based on airline input this will be mostly 737family aircraft. Some wide-body traffic is anticipated from Asian markets, but most new wide-body aircraft will have the range capability to overfly Alaska.

- *Freighter aircraft.* Most of the growth is anticipated to consist of Boeing 747-400 passenger conversions, Boeing 747-800 aircraft and Boeing 777 freighters. Longer-term additional aircraft growth is anticipated from Boeing 777 passenger conversions. By 2030, it is anticipated that some freighter versions of the Airbus A350 and A380 will enter service in the market
- Intra-Alaska aircraft. The heavy-duty turboprop aircraft most useful for this segment are no longer being built. Older 737 aircraft are assumed for those markets with the runway capability to accommodate them. Smaller turboprops (Dash-8s and Saabs) are assumed for those markets with shorter runway capabilities.

Competing Airports

The recommended assumption is that Russian and Central Asian airports will continue to accommodate the bulk of Europe-Asia technical stops. Since virtually all Europe-Asia cargo now goes non-stop or through Central Asia, Alaska airports are not at risk at losing any more traffic from this sector.

From a great-circle distance standpoint, Khabarovsk-Novy Airport (KHV) in Russia and Chitose Airport (CTS) in Japan would have the potential to compete for technical stops on Asia/North America routes. However, it is assumed that environmental concerns and the nighttime curfew will prevent CTS from providing significant competition. It is also assumed that institutional and political concerns will prevent KHV from being a major competitor. As the average range of freighter aircraft increases, it is anticipated that Seoul (ICN) in South Korea will be better able to compete for technical stop and transfer traffic between Southeast Asia and the North American West Coast.

Volcanic Activity

Although episodic events, such as the Mt. Redoubt eruption in 2009, are inevitable, it is assumed that no eruptions will be so intense as to cause carriers to permanently shift flights away from Alaska and the Asia/North America great circle route.

Maximum Acceptable Delay

Based on interviews with the cargo carriers during the previous master plan effort at ANC, the threshold delay (average delay during peak periods in IFR conditions that will cause a carrier to reduce or eliminate its operations at ANC) is recommended to be as follows:

- Express cargo carriers with sort hubs ranging from 5 minutes for Eastbound flights during daylight savings time to 30 minutes for other flights;
- Time definite cargo carriers 30 minutes

• Scheduled passenger carriers. Based on industry standards, a 15-minute *average annual delay* is recommended to be the threshold delay for passenger carriers.

Air Carrier Reaction to Potential Constraints at ANC

Based on interviews with the carriers the following assumed reactions are anticipated.

- All-cargo carriers. Because of restrictions imposed by airport slots and sort operations, integrators have limited flexibility to change schedules in response to congestion. If delays exceed acceptable limits, it is assumed they would take a weight penalty and overfly ANC or seek another technical stop even if it is more expensive.
- *Passenger carriers.* Will adjust schedules to the extent possible given windows of operation and connecting opportunities at origin/destination airports. Passengers from the Lower-48 to FAI will be routed directly and bypass ANC.
- Intra-Alaska carriers. Will adjust schedules to the extent possible given windows of operation and connecting opportunities at origin/destination airports.

Definition of Average Weekday Peak Month

A weekday in July/August is recommended for the average weekday peak month (AWDPM). June through August are all busy months at ANC, but July and August appear to have slightly more heavy operations while June tends to have more GA activity. The later part of the week also tends to be busier than the early part of the week.

Suggested Scenarios

The current study allows for up to four forecast scenarios to be selected by the State in consultation with stakeholders. Some potential scenarios include:

- a) *No-Action Scenario.* This scenario assumes no airfield, parking, or terminal expansion at ANC, FAI, or LHD. This forecast scenario will be performed after the demand/capacity analysis has been completed.
- b) High Fuel Price Scenario. This scenario assumes the U.S. Department of Energy's high fuel price scenario occurs. The impact of higher fuel costs would likely decrease cargo, passenger, and GA activity, and this scenario will estimate the changes in these activity categories for the three airports.
- c) High Economic Growth Scenario. This scenario assumes that the State, U.S., and world economy will grow more rapidly than currently expected. Income and GDP growth rates would correspond to those in the FAA's

optimistic economic and aviation activity forecasts as published in the <u>FAA</u> <u>Aerospace Forecast: Fiscal Years 2011-2031</u>.

- d) *Increased Aircraft Range Scenario*. This scenario assumes that a new generation of all-cargo aircraft (post A380/777F) will provide substantial increases in range without incurring payload penalties. The expected result would be more overflying of Alaska and fewer technical stops.
- e) Complete Elimination of the Bypass Mail or EAS programs. This scenario assumes more radical changes than currently envisioned in the two programs, leading to a complete elimination of service subsidies to Alaska communities.
- f) Star Burst Scenario. This scenario assumes major transfer operations at Alaska international airports resulting in large aircraft coming in from Asia and off-loading cargo to a many smaller aircraft flying to a multitude of North American markets. Under this scenario, the same amount of cargo tonnage as in the baseline forecast will lead to many more aircraft operations.
- g) Significant expansion of North Slope Oil and Gas Development. This would result in substantial increases in passenger and cargo activity to the North Slope, much of which would go through either ANC or FAI.

Other potential scenarios could include lower than expected economic growth, disruptions in Asia-North America trade flows resulting from political instability, trade wars, or major volcanic eruptions, changes in the air cargo fleet mix, or changes in integrated carrier sorting practices.

General

Some key study elements will occur after the preparation of the baseline forecasts. Some of these elements include:

- Trigger points which will identify the activity levels that should trigger key phases of airfield or other capacity improvements, including EIS, design, and construction. Trigger points will be defined after the capacity analysis is complete.
- Potential incentive programs to attract aviation activity from ANC to FAI, and the likely resulting changes in forecast activity at the two airports. This will occur during the strategic analysis piece of this study.
